CLINICAL LECTURE

TUBERCULAR MENINGITIS

Delivered at the Woman's Medical College, Chicago, Ill

BI DANIEL R BROWER, M D,

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM DIDACTIC AND CLINICAL, IN THE WOMAN'S MEDICAL COLLEGE LECTURER ON THE PRACTICE OF MEDICINE IN PUSH MEDICAL COLLEGE, CHICAGO ILL

(Reported by WILLIAM WHITFORD)

The subject for this morning's consideration is tubercular meningitis, basilar meningitis, acute hydrocephalus, an inflammation of the membranes tubercular diathesis miliary tubercles These miliary tubercular demater to be involved in this process vessels, they occur by preference in the area of dis tribution of the Sylvian artery

These miliary tubercles depositing themselves in the walls, contracting the cerebral blood vessels, occur in other vessels at the base of the brain These miliary tubercles are the source of irritation, indicated, and give rise to inflammation of the logical history, and as we shall subsequently see, clinical history of the disease We have first the the stomach deposition of tubercles, producing irritation, interbecomes more and more interfered with, an inflam matory exudation begins to take place, giving rise to the diagnosis the clinical history characteristic of the second stage of the disease The outpouring of serous effusions into the ventricles of the brain gives rise to the symptoms characteristic of the third stage of the disease

Its clinical history is, first the period of invasion, the time when the child begins to be sick from the tubercular meningitis

tubercle is about the size of a millet seed, but by a process of aggregation they may become large masses

A child so troubled begins to be emaciated emaciation especially marked about the lower ex-Children with this disease are usually tremities very bright There is in connection with this miliary tuberculous condition a precocity instance, you take the ordinary form of tuberculosis—phthisis pulmonalis—people so afflicted are often above the average in mental capacity Indeed, some of the most brilliant people the world has ever produced have been, and are, patients with this So in this disease, with such of the brain that has its origin in the deposition of tuberculous inheritance, children are precocious, bright, smart, beyond their years They begin to posits occur mainly in the blood-vessels of the pia be fretful, irritable, peevish, and complaining, noth-It is an uncommon thing for the dura ing satisfies them. While at play, a child so afflicted, he involved in this process. They form in will suddenly stop, and classing its hands to its They form in will suddenly stop, and clasping its hands to its the perivascular spaces and in the walls of the blood- head will cry out with pain. The appetite fails, the tongue becomes a little coated, and sometimes a little thickened in appearance, there is a slight, perceptible rise in the evening temperature, a little cough, a loathing and disgust for food, there is a filling up the perivascular spaces, blocking the blood variation of the pulse, sometimes constipation, and current, give rise to thrombosis, softening of the sometimes diarrhea. The prodromic period of irvessel, and to extravasation of blood They also ritation lasts a month, or perhaps two months, and these symptoms often pass unnoticed by the parents

After a time we begin to have symptoms characthey obstruct the blood current in the way we have teristic of the development of tubercular meningitis—the first stage proper We have as one of its cerebral membranes with subsequent exudations, most striking and early symptoms, vomiting The and to an immense outpouring of serum into the child vomits without any provocation from food, and ventricles, so that we have three stages in the patho- this vomiting is of a most peculiar character, and once seen is never to be forgotten these three stages give rise to three stages in the nausea, but an immense outpouring of fluids from Sometimes the character of the fluid is that of simple mucus, in a word, there is prodigifering with the blood supply Then, later on, as ous, projectile vomiting without any apparent cause the miliary tubercles increase, and the circulation from the injestion of foods This cerebral vomiting unattended by nausea, is an important element in

The child begins to complain of headache, to show signs of intense pain. It puts its hands to its head and cries out frequently with great pain, and this pain, let me say, is of a most intense, excruciating character I think there is no pain so intensely acute, severe, and overwhelming as the headache of deposition of miliary tubercular deposits—deposits or less motor disturbance, and, by the way, we may which are exceedingly small—sometimes so small as state here in passing, that the beginning, the progress, not to be recognized by the naked eye A miliary and order of symptoms of the disease depend largely

deposited If they are deposited primarily in the area of the cerebral artery, the motor disturbance at the outset will be quite marked, manifesting itself in the way of spasms, twitchings of the facial muscles, jerkings of the limbs, muscular tremors, etc. Sometimes when the disease commences in this area, and is progressing rapidly, epileptiform convulsions are Then, at about this time, certain ushered in sensory disturbances manifest themselves, there is general hyperæsthesia, a great intolerance of lights and of sound, the pupil is contracted, the child is intolerant of the least possible effort at movement, walking across the room will give it intense pain Frequently, we have too, certain psychical symptoms, evidences of mental disturbance If the deposition of miliary tubercles begins or takes place in the anterior cerebrum, the area of disturbance being there, it has more to do with the intellectual manifestations of the patient, and the psychical symptoms are early and prominent ones. The child becomes more emotional and irritable, a little delirium begins to show itself just as the child is going to sleep or waking up When it awakens, it does so with an intense cry—a cry so heart-rending and peculiar that it has been called the "hydrocephalic cry"

We find a disturbance in the vaso motor area of If you take your finger nail the nervous system and draw it over the thoracic and abdominal areas, especially where the two areas unite, it will speedily below normal, the fever disappears, the pulse bebe followed by a bright red line that will remain there for, perhaps, several moments—the "tache ular, and we have that respiration characteristic of cerebrale" of Trousseau While it is not pathogno- pressure made upon the medulla, the so-called monic of tubercular meningitis, yet it is rarely found in any other disease of the body that does not involve this inflammatory, irritative condition of the cerebral membranes It is the beginning of this This "tache cerebrale" is form of nervous disease found early, and is the result of interference with the activity of the vaso-motor nervous system

The abdomen at this time presents a peculiar "boat-shaped" appearance, an important point in the diagnosis, from the fact that in other infantile diseases which closely resemble tubercular meningitis, it is usually found tympanitic, distended, but in this disease it is retracted, the umbilious is thrown well back towards the spinal column, so that it presents what is admirably termed "a boat-shaped appearance "

The temperature of the disease is well worthy There is from the beyour careful consideration ginning of the prodromal period a slight rise in temperature, and when the first stage of the disease has become established, the evening temperature will be found to be one or two degrees higher than that of the morning, but it rarely ever rises above 103°, except when the disease is about to terminate fatally The exacerbations and remissions are irregular, they do not pursue that regular, uniform course which is characteristeric of the disease that closely resembles it, namely, remittent fever pulse is important in the beginning of the disease It is usually full, compressible, regular During the minute, and associated with this great rapidity of the stage of irritation, when you have the vomiting, to pulse is more or less irregularity, the beats are not

upon the place where the miliary tubercles are first which I have alluded, and sensory disturbance, the pulse, as a rule, is regular, and not unduly fast, which is another important aid in the differential diagnosis Respirations are regular, and become more rapid than normal in the early history of the During the primary stage, we have another symptom of great value, and that is constipation of a very obstinate character Ordinary doses of laxatives are entirely inefficient to overcome it

Now, as the disease progresses, and the exudations begin to appear, a change manifests itself in the symptoms, and in the majority of cases you will flatter yourselves that your treatment has been a success, and that your patient is convalescing The vomiting ceases, the headache disappears, the muscular spasms and convulsive movements cease to a greater or less extent, the child is no longer intolerant of light and of sound, the contracted pupil begins to become normal in character, and for a few days it would seem the patient was certainly getting better But very suddenly there comes an increase in the mental hebetude, an increase in all the psychical symptoms The delirium becomes more marked, the tendency to sleep becomes greater, and the child loses almost altogether its active responses to external impressions, it becomes, in a word, dull, heavy, soporous Along with this condition, we have alterations in temperature The characteristic remissions of the first stage disappear, the temperature, as a rule, falls comes slow and irregular, respirations become irreg-"Cheyne-Stokes respiration," which consists in a respiratory manifestation by a series of cadences The respiration will be normal in one or two movements, and then the depth of the movements will seem to increase, and the interval between the respiratory connections increases until the respirations gradually fade away, and for several seconds cease, after which they again become more manifest interval will be shortened in its duration, the respiratory action will be increased until they again become normal, following which is a retrocession, until the respiratory action ceases, and so the respiratory phenomena continue The peculiar character of the respirations will, as a rule, manifest itself at night During the whole day the respirations will, perhaps, be normal, but as night approaches this peculiar, medullary respiratory action, characteristic of pressure made upon the medulla, and named after the two distinguished pathologists, Cheyne and Stokes, Exudation has been going on, the effucomes on sion of serum has increased, and we gradually begin to get more pressure upon the important structures at the base of the brain, and as a consequence we have a very great increase in the comatose condi-It becomes now almost impossible to arouse the child, and along with this increased coma there occurs a very remarkable change in the pulse The condition of the pulse, which had been normal, now becomes exceedingly frequent, reaching from 150 to 170 beats in a

During this stage of the dis of the same intensity ease the spasms that characterize the motor disturb ance at the outset develop into paralysis You will find one side of the face, or some member of the body, such as an arm, or a leg, or both, paralyzed Just before death ensues, as a rule, we have decided elevation of temperature, the temperature frequently running to 105°, and paralysis before the scene closes becomes generally diffused

Now, as to certain points in the diagnosis of this It is hable to be mistaken for ordinary acute meningitis, for gastro enteritis, for infantile remittent fever, for acute Bright's disease We told you at the beginning of the lecture that tubercular meningitis was basilir, that the base of the brain was involved in the pathological processes most uncommon thing to find any of these miliary The convexity of tubercles elsewhere in the brain the brain escapes, except in so far as it becomes involved later along from pressure of serous and puru lent exudations

A surface thermometer will aid you in diagnosis There is a certain fixed relation, in a state of health, between the temperature of different parts of the head, as rudely shown in this hastily prepared dia-Taking the left side of the brain, we have here (illustrating) three areas designated, the frontal, the parietal, and occipital, corresponding to the three divisions of the surface of the cerebrum peratures shown in the diagram are determined by examination of different classes of people in Brooklyn and New York, by the distinguished specialist, Dr Gray In the temporal region, as you see, the temperature is 94 2°, over the parietal, 94 3°, in the occipital, 92 3° On the right side the tempera tures are generally lower, the right side, of course, having less functional cerebral activity than the left The frontal temperatures are lower than those of the occipital in tubercular meningitis. The relation is disturbed The occipital area is where the disease spends its force largely The relations of the areas

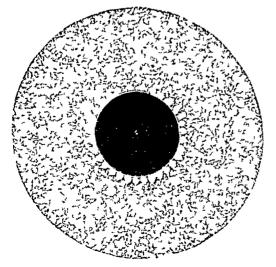

Diagram 1 Wreath of white clouds

symptoms enumerated, will serve to make the diagnosis clear We have also, in the first stage of the disease, a contracted, mobile pupil In the second stage the pupil dilates a little, is immobile and insensible, so far as contact with light is concerned There is not only dilatation of the pupil, but certain important changes take place around the pupillary margin About the sixteenth of an inch or less from the margin proper there begins to form a distinct wreath of white clouds (see diagram 1), doubtless due—as has been determined by Dr John D Skeer, of this city, who was the first physician to discover this pathognomonic symptom—to changes in the iris and the deposition of minute, miliary tubercles upon the vessels Now this is to be seen only in the incipient stage of the disease, and when you have associated with the symptoms we have described, this characteristic condition of the iris, you are absolutely certain of your diagnosis of tubercular meningitis. Unfortunately, this symptom is not always present, just as other classical symptoms are sometimes absent in other If this condition of cloudiness around the pupillary margin happens to be present, after three or four days it begins to disappear Instead of minute, cloud-like masses, we have a yellowish brown circle (see diagram 2), this change taking

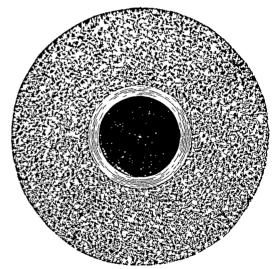

Diagram 2 I ellowish brown circle

place at the beginning of the second stage, due, doubtless, to degeneration of the blood vessels and tissues as a consequence of the presence of miliary tubercular deposits In the third stage this yellowish brown circle becomes very much attenuated by the dilatation (see diagram 3) of the pupil seems to be, in addition to the miliary tubercular deposit, a destruction of the circular muscular fibres of the iris, the pupil ceases to be responsive to light, it becomes immovable Then, too, the ophthalmoscope is a very valuable aid in the diagnosis during the primary stage of the disease If you examine the vessels of the retina with an ophthalmoscope you will find venous stasis of the blood-vessels, they appear tortuous and enlarged, you will find miliary tubercuthen are disturbed, and this, associated with the other lar deposits in the choroid, and later along in conseexisting there, you will have a neuro retinitis

from the signs we have mentioned, is the slow, insidi- low, in tubercular meningitis it is great, and the conous onset of the disease slowly, but tubercular meningitis comes on in a slow, insidious way, the prodromal stage requiring, as a rule, a week or ten days, sometimes even a longer

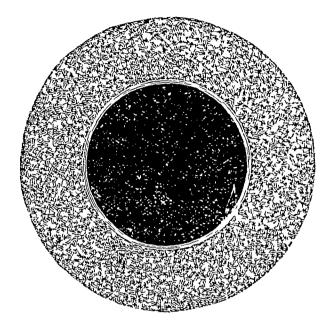

Diagram 3 Pupil dilated

Tubercular meningitis rarely ever period than this occurs before the age of 2 years, and rarely occurs If the child is over 7 or under 2 after the age of 7 years, the probabilities are against a tubercular form of the disease

Its differentiation from gastro-enteritis is made by the boat-shaped appearance of the abdomen, and the presence of the other pathognomonic symptoms here described

The most perplexing of all diseases, I think, is re-More mistakes have doubtless been made in the differentiation here than in all the other Of course, when diseases which it closely resembles we have the head symptoms, the spasms, pain, rise in temperature, etc, together with the pupillary changes, we can easily differentiate the case when the three several pathognomonic symptoms are not observed, or observable, then differentiation be-To repeat the differentiation comes more difficult is to be made mainly by the fact that tubercular men ingitis shows a boat shaped abdomen, and an obsti This disease shows a temperature nate constipation like that of remittent fever, but lacking its regularity The vomiting in tubercular meningitis differs from that of remittent fever in that it is a vomiting without nausea-indeed, without any evidence whatever of any gastric disturbance, the tongue has little or no fur upon it, whereas the tongue in a case of remittent fever is very foul and thick

Errors in differentiation of tubercular meningitis from spurious hydrocephalus may arise, but the histonosis easy If the child is young, you have in spuri- this comparatively modern treatment to know of its

quence of the progress of the inflammatory changes ous hydrocephalus a depressed fontanelle, in the disease under consideration an elevated fontanelle Another point in the differential diagnosis, apart In spurious hydrocephalus intracranial pressure is Acute meningitis develops dition of the fontanelles will enable you to differentiate it

> The prognosis of the disease is very bad sional recoveries take place, but they are exceedingly few and far between Yet there are cases on record where post-mortem examinations have revealed the fact that death resulted from other causes than those characteristic of tubercular meningitis, especially in the history of a form of insanity to which your attention will be directed later on, which gives us reason to believe that occasionally the disease is recovered Many physicians who see the cases of recovery from tubercular meningitis will tell us that we erred in diagnosis, that it was simple meningitis, and

> The duration of the disease is from 16 to 21 days, except in those cases that are ushered in by convul-Then, of course, the duration is very short

> The most important element in the treatment is that which is prophylactic, which takes the child from its birth, knowing its tubercular diathesis, and by Judicious, hygienic measures overcomes its tenden-It involves a treatment for the eradication of the tubercular diathesis, fresh air, sunshine, nutritious food, careful attention being paid to elimination, the use of mild alteratives, etc

In connection with the tubercular diathesis we must necessarily have an exciting cause or causes, and among some of them are the ordinary febrile diseases of children—the exanthemata, for instance -especially measles, which is a fruitful exciting cause Children with a tubercular inheritance should be carefully guarded against such affections as ordinary whooping cough, otorrhea, etc, which are very common among children, and if any one of these diseases should occur, it should be vigorously treated There is, unfortunately, a notion among the laity, especially the more ignorant class, that discharges from the ear are more wholesome than otherwise, and sometimes such a condition is allowed to go on without attention being paid towards early and prompt treatment Children should be guarded also But against injuries of the head The majority of cases that have come under our notice have been the results of muries of the head

When the disease has once become established, the treatment to day that is regarded by those who have had the largest experience as the most scientific and likely to give better results than anything heretofore proposed, or brought before the profession, and holds out the most encouragement—and it is not worth our while to mention the numerous lines of treatment that have proved inefficient—is the treatment by inunctions of iodoform—iodoform and lanoline or vaseline, about 1 part of iodoform to 5 of the vehicle Make an application of iodoform inunctions at least twice daily to the scalp, the head being shaved for the purpose, and the scalp being covered ry of the later disease, in some cases, makes the diag- with an impermeable cap We have seen enough of practical value if the iodoform inunction treatment is used early in tubercular meningitis, the proportion of recoveries will be much larger To allay the intense motor and sensory disturbances, opium is indicated, and the bromide of potassium To relieve the congestion of the blood vessels of the hard, elimination by the bowels is indicated, and laxatives, diuretics, etc., may be given

ORIGINAL ARTICLES.

STATE REGULATION OF THE PRACTICE OF MEDI-CINE-ITS VALUE AND IMPORTANCE

Read in the Section on State Medicine, at the Thirty Lighth Annual Meeting of the American Medical Association, June, 1887

> BY II C MARKHAM, MD, OF INDEPENDENCE IOWA

Experience has demonstrated that genuine scientific culture is everywhere productive of a cast of mind averse to abrupt innovation or the acceptance of an unproven principle or theory This characteristic as existing in the body of the medical profession. has in the past operated adversely to the acceptance legal or State regulation of medical practice in any political expedient—as its potent success abroad exist fully proves—it receives the aspects referred to when applied to States having the peculiarities of social and political systems possessed by those whose citizens we are

Irregular and criminal practice has so intrenched itself, and become so closely interwoven in our social fabric, that only the most judicious and united effort, presents any hope for the erection of a legal barrier adequate to the accomplishment of its object, which latter is the protection of the public

The aggregation and concentration of population is productive of danger to life and health, the removal of which is the unquestioned duty of the State To those familiar with the subject it is scarcely necessary to state that the history in various of our States of attempts to secure legislation for the regulation of the practice of medicine, presents little other than a For several years a small number of philanmaintained the unequal contest with the hosts of ignorance and charlatanism—while the main body of ultimately required and frequently with open criticism, declined to ren- National governments der the assistance upon which success depended

We have a case now under is, in its influence, a most serious misconception of observation recovering from its use, and know of the actual object of the legislation in question. Even two or three cases of the fatal form in which life at the present time it is no uncommon thing to hear was prolonged very much beyond the ordinary from the lips of members of the profession who, in limit by its application. It is the impression now that ability and usefulness, are high in rank, the remark that it is only a question of "the survival of the fittest"—that "scientific medicine deserves disgrace and defeat if unable to stand against quackery" This terse expression of the behef of our brethren betrays the mexplicable erroneousness of their idea of the absolute purpose of this legislation object is the furtherance of class and even of school interests, is a misconception of the animus of the champions of this legislation which its opponents have discovered to be their most powerful weapon

That medical men, by virtue of their calling, are alone competent to measure the evils against which this legislation is aimed, should be its chief promoters, is but commendatory, rather than aspersive, as is The conditions of alleged, of their championship modern life necessitate the expansion and broadening of the historic self sacrificing exercise of charity by medicine toward the individual sufficient to include the public Rightfully or not the latter holds the regular profession responsible for its security against imposition and fraud. State regulation of practice implies the responsibility of the former to institute the method best suited to secure its success The best light available directs us to that system which invests a Commission or Board to examine, decide, and grant or refuse, as the applicants fitness may determine, a permit to practice fitness of the material composing a Board of the of a belief in the principle or practical wisdom of a kind, much but not all depends. The inadequacy of result may, and will rest in the imperfection of the While by no means an experiment or a new law under which they act should such imperfection So strongly intrenched is medical error that it can be overcome only by gradual approaches The danger of failure is lack of patience and All depends upon securing the first advan-So salutary are the effects of this legislation that public approval attests, but will always await their display

That guilt makes cowards of medical pretenders found ample verification in the exodus of hordes of this ilk to adjacent States upon the adoption by the State of Illinois of its present medical practice act Iowa has more recently enjoyed a similar experience As by a miracle towns awoke to find themselves wholly destitute of medical talent. No better endorsement of the law is possible than the resignation exhibited by citizens under such affliction upon being apprised of the cause Uniformity of the standard of qualification adopted by the licensing power of long panorama of heroic endeavor and humiliating the different States, should enable the certificate of any one to be honored by all A central or interthropists from the ranks of scientific medicine have state commission, chosen by the President, equally from the army and civil ranks of practice will be No more is a department of their professional brethren have with folded arms, Justice than of medicine demanded in our State and

To this end the one and all essential prere-The chief obstacle obstructing a proper view of their quisite is the united, earnest and cordial effort of the duty, and more especially that of the public at large, profession in the various States The momentum given by the movement of one should not be lost by mon, and of such only Where the organization of the maction of others The path is thorny and those we labor to rescue too often chill us by that most cruel of wounds, the impugnment of motive, and so slow must our progress prove that only those coming after shall enter the promised land of a redeemed Experience has conclusively shown that at the present time public opinion in some of the States will not permit the suppression of a class of practitioners who, unqualified in various respects, have for a considerable period of time succeeded in concealing the fact from the public This is more than compensated for in the fact that no difficulty is met in rigorously excluding from State limits all foreign incompetents, and as recently stated by the efficient Secretary of the Iowa Board of State Medical Examiners, who says "we have put up the bars most effectually, and if nothing more were gained could afford to wait upon the gradual clearing by what might be termed precipitation by death of the somewhat turbid mixture which is now legally recognized as medical practice "

The Christian and moralist outside the medical ranks have yet to be convinced of the vital impor tance of this legislation to the purity and welfare of our social fabric Everywhere the success of crime is promoted by insidious and concealed attack with fœticide and infanticide, and no prophetic vision is needed, especially by those of our calling, to see the effect upon the home and family of these at present unchecked crimes Beneath the fair white folds of the emblems of the healing art the black flag of the abortionist has always found an easy conceal-To strip the mask from off these interlopers and drive them from the field is required the aid of legislation moulded by those whose knowledge of the situation equips them for the task The numerical decline of the typical and peerless American family, finds fortunate compensation in the rapid increase of the average duration of the life of its members, and a brilliant triumph of our brethren, with others, in the field of sanitary science, and significant in this connection as having been largely accomplished by their wise invocation of efficient legislation

Sanitary science, properly a branch of the healing art, at the present is the vine, medical apathy making itself the branch The same lusus naturæ occurs in several States where our pharmaceutical branch has become not only the vine but the husbandman, having even an alleged disposition to set us down as cumberers of their ground Through the influence insured by and resulting from compact organization, it is made the dictum of their law that a drug upon the shelf is more dangerous to the public than it is when occupying the interior of the victim of ignorant administration Thou shalt For saith the law not sell, but all may administer The term "all" includes, when thus emphasized, our pharmaceutical friends, who appear unsatisfied with the glory resulting from an alliance with that army of conquerors of death and disease whose patented weapons, in glittering array, ornament the shelves of our "legally registered friends " Identity of interest, as that of medicine and pharmacy, admits of legislation in com- elevation of error, and the history of all successful phil-

each is adequate it would be wise, by delegated committees, to seek a plan for the restoration of the oldtime unity of relationship the lack of which, as shown by recent experience, is most detrimental to both States having as yet no proper medical practice or pharmacy law will, by adopting primarily an offensive and defensive alliance of the two callings, thus uniting their strength and interests, secure escape from many obstacles that otherwise would present themselves

The success of the new "Practice Act" of Iowa fully equals the anticipations of its promotors, and has in numerous cases secured the approval of those previously doubtful of its wisdom Before fully operative it induced numbers of those who in public esteem were as deeply rooted in practice as they were towering above other earthly beings, to accept urgent proposals to locate elsewhere Many others determined to remove the rust of years from the once dazzling surface of their collegiate armor, but invariably selected for such polishing one of the colleges duly accredited by the Examining Board of the State It will be noted here, in passing, that this law necessarily establishes the much desired scientific standard of medical institutions of learning also lengthen the list of matriculants of meritorious schools and aid in the extinction of the crop of incorporated blotches whose nefarious avocation has made the exhibition or possession of a medical diploma little other, in the eyes of the public at least, The number of medthan a cheap confidence trick ical pretenders driven from the State of Iowa since the adoption of the Practice Act, scarcely one year since, cannot, of course, be accurately ascertained suffice it to state that it is satisfactorily large law is, in the nature of things, far from being perfect

The objectionable but indispensable feature by which a term of practice in one locality entitles such practitioner to a legal status, is less an objection than its prima facie appearance indicates The records of the Iowa Board show that four fifths of this class of licentiates are certified to as reputable citizenssuch being one of the conditions in the application to said Board-by members of the State Medical Society of Iowa It is also true that prominent and efficient members of the same Society are of the class to which objection is taken Some of these found themselves able to take but two out of three contemplated courses of lectures Others were ill at date of college graduation, and thus were minus the degree which, until the present, was dispensed with at little inconvenience

It is a consideration of practical importance that every licentiate of this class becomes, by virtue of such benefit, a recruit for the further prosecution of the legal extermination of pretenders in medicine It is found that the first step for the protection of the public against fraud and crime in medical guise is attended by a loud clamor for various school representation upon committees or boards created by the Recognition of such claims or proposed legislation men is not their endorsement. There can be no true giant and deep rooted evils has this one feature of their inception stage, a feature often termed compromise, but which with more truth may be called "ra tional concession " Those whose duty is the framing or amending the terms of practice legislation can well afford to consider the problem of the execution of the terms of such legislation, when once enacted Law is never self enforcing, and but few of us relish average citizen the most dearly purchased and essential systems of A violator of the law or legislation have foundered a nuisance whose existence, as that of an infectious disease or death exhaling pool, needs only to be made known to the usual health officer of the district, town or city

As a matter of economy to the State, not to men tion that of necessity, the functions of Health and Practice State Boards should be combined material portion of the machinery of a health department is the appointment in every township of a health official, it should be a provision of the prac tice act that such health officer should, upon being notified, institute proceedings for the arrest and pun ishment of violators of the law Finally, whatever little of practical value may characterize the foregoing, it will have realized its purpose if any impetus or increased interest is added to this our new crusade for the expulsion from the sacred precincts of our several States of the vandal desecrators who, in the guise of true disciples of the healing art, would im peril and ruin home, health, and the happiness of our people and-not the least of all-craftily degrade in public esteem the fair fabric of medicine, over whose vestibule are the words honor, science

A CASE OF RUPTURE OF THE INTERNAL CAROTID ARTERY WITHIN THE CAVERNOUS SINUS

Pulsating Exophthalmus, Ligation of the Internal Carotid Artery Death Autopsy

Read in the Section on Ophthalmology and Otology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY CORNELIUS WILLIAMS, M D, OF ST PAUL MINN

This case is one of exceeding interest, not only because of its rarity but because of its intrinsic im portance and gravity The disease is so rare that in the combined experience of a dozen surgeons of a very large practice it might not be met with once, yet when it does occur it is highly important that it should be recognized and properly treated

The distinguished author of the article on "Pulsating Exophthalmus" in Grafe and Samisch's "Hand book," H Sattler, was only able to collect 106 cases in the literature of the world for a period of more than 70 years In the table that he constructed a num-

anthropic and political methods for the extinction of are that some other lesion was the disturbing factor, but in the majority of cases he has demonstrated that rupture of the internal carotid within the cavernous sinus was the foundation and origin of the exophthalmus

In a certain percentage of cases the disease was practically allowed to take its course and resulted in This termination, it may be assumed, is the natural outcome of rupture of the internal carotid the task of the informer and complainant, wherein in this location, when things are left to themselves, our own interests play no part other than of the or, what is the same thing, when any other treatment It is this rock upon which some of save the most radical is adopted The conditions that govern the result of all surgical operations are, of course, in operation here, and the best directed medical swindler might be treated in one respect as efforts of the surgeon may fail, as was the case here, through no fault of the surgeon himself

On February 8, 1887, Dr J A DuBois, of Sauk Center, Minn, sent James Homm, at 27, to me for treatment The patient was a man of large frame, good muscular development, had never had any venereal disease, had always been in good health, but by his own confession and from the statement of the physician, he has been a very hard drinker Christmas time he was awakened one night by a fit of violent vomiting and retching, which continued almost without interruption from 11 o'clock at night to 2 P M the next day The retching was so violent that it seemed to the patient that every minute must be his last Very soon afterwards he became conscious of intense pain in the left side of his head and ear, together with a whizzing, whirring noise which was so loud that it seemed strange to him that others did not hear it too The patient, who lived on a farm near Sauk Center, was not seen by any medical man at the beginning of the attack, and when, after some days, he was seen by Dr McMasters, of Sauk Center, the left eye was protruding, with the lid dis-The man was drinking heavily, and so concolored tinued until I saw him

February 8, 1887 Left eye markedly prominent, lids puffy and blue, the episcleral vessels enlarged and full, chemosis of conjunctiva, pupil dilated, media Retinal veins enlarged and tortuous, neuroretinitis, no hæmorrhages

 $V_{\frac{20}{30}}$, Em Right eye, $V_{\frac{20}{30}}$, Em Auscultation of the eyeball and side of the head disclosed a loud bruit, continuous, with an accession that was synchronous with the first sound of the heart bruit was heard not only over the left side everywhere with great distinctness but all over the head, with greatest distinctness over the left eye and next over the left temporal region, nothing of interest in The patient was seen at my request by Dr Brisbine, Dr Miller, Dr Witherle, Dr Carl Schulin, Dr Wood, and a number of others, all of whom distinctly heard the bruit and felt the thrill that was appreciable when the ear was held to the temple All bruit stopped on firm pressure applied over the common carotid The patient was placed under observation in St Joseph's Hospital Some two weeks after his admission there, for the first time I was able to perceive pulsation of the eyeball, which was obber of cases are included in which the probabilities was perceptible to the touch when the eye was served when the eye was examined in profile, and

crowded into its socket, or when the finger was forced into the orbit

About this time, too, a small oblong tumor, somewhat curved in outline, near the size of the little finger of a child, appeared just below the lower lid and toward the inner angle This tumor pulsated, was easily compressible, and of bluish color, pulsation was not to be felt by the finger

Four weeks after the entrance of the patient into the hospital Dr E J Abbott, at my request, ligated the left common carotid, in which he was assisted by Dr Wm Davis, Dr Stamm, Dr Shimonek and oth-The ligation was effected without accident and with no unusual damage to the sheath of the artery A double ligature of catgut was applied, the artery The temporal pulse on that side ceased immediately, as did the bruit and the thrill, this cessation was complete and permanent The external wound was closed with silk sutures, after washing with bichloride of mercury solution, 1 to 2,000

On the tenth day the wound had entirely closed save a small pocket at the lower angle, where there had been a small collection of healthy pus No bruit or pulsation had returned Retinal arteries very small, veins still large, neuro retinitis the same, vision very poor, pupil dilated, chemosis and congestion less, exophthalmus less marked, less discoloration of The only general symptom of account was an irregular pulse with some fever at the time the The third day after the operation, abscess formed small doses of whiskey and digitalis were given and these symptoms soon disappeared On this day, the tenth, the patient got up, dressed and walked around It is not known just how long he was up, but the sister in charge was summoned hastily and found the man bleeding furiously from the wound and drenched She with great presence of mind placed her finger in the wound and stopped the bleeding by pressure Dr Abbott and myself were summoned by the house surgeon, when Dr Abbott, assisted by Dr Renz and Dr O'Hage, reopened the wound and tied both ends of the artery, which was found to have ulcerated through between the ligatures No attempt at the formation of a permanent clot could be ascertained, and the artery presented much the appearance of a piece of white rubber tubing The religation of the artery was attended by immense difficulty because of the swelling and matting to gether of the tissues, night came on and we had only a lamp to work by There was no hæmorrhage from the proximal end of the artery during the second operation, but when the surgeon came to look for the distal end after ligation of the proximal, the hæmorrhage all at once came on and for a little while was terrible

The patient never recovered from the effects of the hæmorrlrage On the third day thereafter he became hemiplegic, and soon afterwards aphasic This condition continued for a week, when he died In order to have any post-mortem examination at all it was necessary to make it at once, as the friends of the patients desired to take the body home for burial, and would leave in a few hours The eye that had protruded was now as much sunken in the socket as rectly, to the effect that the exophthalmus, the tur-

the other The skull was opened by Drs Abbott and Shimonek, half an hour after death There were some evidences of a pachymeningitis over the ver-The sinuses were well filled with dark fluid The brain was removed and carefully sliced blood off from above downward A large portion of the left anterior hemisphere was found to be converted into a soft pulp of about the consistence and appearance of very soft fromage de brie, brain otherwise The internal carotid, from its entrance into normal the cranial cavity, was examined without the discovery of anything abnormal in its gross appearance It was the intention to have saved it for further examination but, unfortunately, it was included with the brain substance and sent away with the body The posterior wall of the orbit was chiseled away and the orbital coutents carefully examined by myself Nothing abnormal was found, except perhaps some increase of the adipose tissue The ophthalmic vein may have been somewhat enlarged, but it was not compared with the vein of the other side wound in the neck was covered on its inner surface with a dirty slime, with no appearance of any attempt The ligature of the distal end at repair whatever of the artery had sloughed off partly, and doubtless, had there been sufficient heart force, the man would have had another hæmorrhage

As unsatisfactory as is the result of this post-mor-The only tem examination, it teaches a great deal two pathological conditions which could by any possibility, I think, give rise to the physical condition which existed in this case, are aneurism of the internal carotid within the cranium, or rupture of the internal carotid within the sinus cavernosus Aneurism of any vessel within the orbit could not give rise to all the symptoms, besides, by continued observation lasting a month I had excluded that condition, which I was anxious to find Any malignant or other tumor of whatever nature was likewise excluded tween an aneurism and a rupture of the internal carotid, the chances are always in favor of the existence of a rupture In proportion to the number of cases observed, and where post-mortem section has been made, the cases of rupture are far more numer-Aneurism of an intracranial artery is by far less frequent, in general, than rupture The anatomical difference in the arterial coats here and in other parts of the body may account for it The lesson of the artery within the sinus constitutes the salvation of the patient, it is the accident of position which determines whether the patient shall die instantly, perhaps, from a hæmorrhage into the brain tissue, or whether the peculiar complex of symptoms which constitutes pulsating exophthalmus shall supervene There is one condition which was present in my case which has been mentioned as also occurring in other cases published that is, the small pulsating tumor It did not occur to me with under the lower eyelid equal force at the time, but afterwards it seemed to me that its presence and character may be sufficient to enable us to make a differential diagnosis between aneurism and rupture of the internal carotid

H Sattler has reasoned, and I think most cor-

gescence of the veins of the eye and the lid, etc., none of the usual symptoms of a perinephritic abinto the sinus with each pulsation of the heart. This tumor is simply an exposed vein, enlarged at this point and receiving in its contents in impulse with in the bladder each influx of arterial blood into the sinus Now, if tumor, when it occurs, will always pulsate, a soft, compressible, pulsating tumor not communicating an impulse to the finger Such a condition could not result from mere pressure, but must depend upon regurgitation Only an inflow of arterial blood into the sinus can occasion pulsating regurgitation

As to the failure to find the gross appearances of a rupture of the artery at the post mortem, that does not prove that there had been none I doubt if an actual lesion of integrity will ever be found where as long a time has elapsed from the making of the oper had been the case here There is ample time for a tear in the arterial coats to have healed perfectly, if at rest, in apposition, and no interference with nutrition in the immediate vicinity Only an examination under a lens will disclose the scar there

In regard to the hæmorrhage, it is impossible to say positively that it would have occurred if the pa tient had been entirely prudent. It is possible that, if undisturbed, a clot may have formed and organ-Certain it is that the great loss of blood, low ering the general nutrition and acting on the area of brain already much lowered in vitality, assisted in the production of softening from malnutrition and thus brought on the fatal result

A CASE OF NEPHRECTOMY

Read before the Chicago Medical Society, Nov 7, 1887 BY CHARLES T PAKKES, M D,

PROFESSOR OF SURGERY RUSH MEDICAL COLIEGE ATTYNDING SURGEON TO THE PRESBYTERIAN HOSPITAL CHICAGO

Last July I received a communication from a friend out of the city, stating that a patient had come under his charge who had been suffering for two years with cystitis, the diagnosis being based

upon pus in the urine

When I returned from my vacation in September, I found the patient awaiting me at one of the hos pitals in the city Upon examination it was found that a tumor could be easily palpated in the right side of the body beneath the ribs, large enough to extend down to the superior spinous fossa of the ileum, and reaching up to the hypogastric region be low the liver and percussion, the dulness over the tumor was found to be continuous with the dulness of the liver But the tumor appeared to me to be so elastic as to present some of the characteristics of a sac contain So I introduced an aspirator needle into

are all due to an overfilling of the veins from regur- scess, it was diagnosticated to be a case of suppuragitation of blood from the sinus cavernosus, and he tive disease of the kidney communicating with the shows how this may readily occur, given a rupture bladder through the ureter, the bladder being the of the artery, with consequent influx of arterial blood outlet of the pus. There was no apparent disease of the bladder itself, other than that which would be present as a consequence of the foreign substance

Obtaining the patient's consent to an operation, there is a rupture of the artery within the sinus, the an incision was made over the tumor to the outside of the erector spine muscle, and it was exposed, then the pockets of pus in the organ were located by the hypodermic syringe On this occasion, three pockets of considerable size were opened, and drainage tubes introduced About a pint of matter was let out It was decided that these three pockets, that were found by introducing the syringe in different places, did not communicate with each other. they were separate cavities, and I think that is the usual condition found in this sort of disease of the

kidneys, the pockets are multilocular

One of them opened freely into the pelvis of the ation to the making of the post mortem section as kidney, so that through the incision that was made the finger passed into the pelvis, and water injected into this went into the bladder, showing that there was a direct communication from this cavity of pus to the bladder and urethra The drainage tubes were left in and the patient improved promptly, losing the fever and symptoms of pus accumulation and retention For two weeks the improvement continued, then it was noticed that she began to fail rather rapidly and to show signs of fever again, there were signs of septic accumulation, and the tumor began to increase in size, so that from diminishing, perhaps half the size when first examined, it increased one third As she was failing and the diagnosis was as complete as it was possible to make it, it was decided to perform nephrectomy

There are some points of importance in the case The drainage tube that went into the pelvis of the kidney gave free exit to quite a quanity of urine I think that most of the secretion from that kidney came through the drainage tube, it was sufficient to wet thoroughly in two or three hours a large dressing, this dressing was sufficient to keep the discharge from the wound pure so that there was nowhere decomposition of pus so far as the outward manifestations were concerned It struck me that if this drainage tube from the diseased kidney gave exit to such an amount of urine, and at the same time there was a good flow of urine from the bladder, it was a fair indication that the other kidney was not diseased, and that success would attend the removal of the diseased kidney, and it was decided to do the operation

Sixteen days ago the operation was done patient was prepared in a certain way that I have Upon the usual attempts at palpation followed in reference to all patients upon whom I do what is considered a serious operation, and I think it has a certain influence in preventing shock. Two or three hours before the operation is performed

the patient is given gr v to x of quinine, and gr 1/4 of morphine This medicine was administered to 1t, and as was expected, found pus As it presented the patient of whom I am speaking, and the opera-

tion for the removal of the kidney was performed The whole proceeding from beginning to end occupied an hour, and she went to bed without any manifestation of shock, and with a pulse of 112 had no rise of temperature until the second day, and then it rose to 100°, subsequent to that it fell to normal and did not rise above normal until the first incision and half way between the crest of the twelfth day, when other symptoms appeared ing all this time the wound was absolutely aseptic It healed promptly by first intention, so that on the seventh day all stitches were removed, the wound was solid from one end to the other

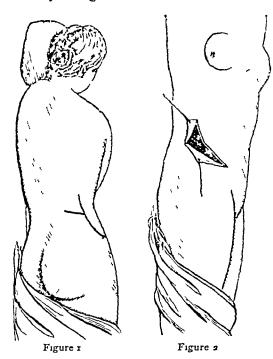

There are some points about this operation to which I desire to call your attention, and I will pass the specimen around to show the nature of the You will see at the lower end a cavity, which was found to contain six or eight ounces of pus, there is another cavity in the interior of the kidney, the pelvis is entirely destroyed and filled up with adventitious material

Here was an operation to be done upon a mod erately sized woman for the removal of a tumor containing pus, a tumor which reached up under the ribs, down to the crest of the ilium, and forward to the anterior spinous process There was a tumor containing pus in which large pockets had formedwhat was the best way to remove it? There is no question in my mind that the best operation, in general, for the removal of the kidneys is the posterior However, there are many diseases for operation which this operation is done where it is impossible to do it in another way than by the anterior operation, such as cases of cystic degeneration where the tumor is so large that it cannot be extruded posteriorly, but here was a tumor of moderate size, containing pus, in which it was desired above all things to avoid getting into the peritoneal cavity, a tumor which had sacs, the walls of which were in moderate incision was made the tumor presented itself, the degrees of thickness and strength, but could easily be broken upon pressure

Therefore, the day before the operation I took a cadaver and experimented upon the lines of incision which would best expose this tumor and give I finally decided upon the incisions represented in Figure 1 This represents the patient lying upon the opposite side from the diseased In these experiments I found that by a certain incision I could get the amplest room without doing injury to the colon or peritoneum, certainly no more likely to injure the colon, the peritoneum or other contents of the abdominal cavity than in an operation for the exposure of any of the large blood vessels of the abdomen

It is hardly necessary for me to state that there is some little difference between subserous tissue in the lower portion of the abdomen and that of the In the lower portion it is very loose and easily separated, whereas at the upper portion it is large cavity but the track of the drainage tube quite thin and the peritoneum is more apt to be torn, hence more care should be used in an operation | me, of the safety of the posterior incision for tumors in this position cision is supposed to be two inches above the an- carried out, somewhat in the way here indicated terior superior spine of the ilium curved direction downwards and backwards to the days ago this patient was taken with symptoms of

last rib The incision is carried through all the tissues, down to the fascia transversalis, everything is carried forward out of the way, and with the finger the dissection can be made, well behind the tumor. all the parts are separated, then a straight incision is made through all of them, straight back from the ilium and the last rib The introduction of a ligature at the point of the posterior flap, and pulling aside, there is a wound one can get both hands into and by exposing the kidney in all its parts, reach the tissues which one wishes to have under control, without difficulty Figure 2 In this case as soon as the

finger could be carried around it in all directions so that the kidney with its blood-vessels, ureter, and all could be exposed to view

I desired to adopt the plan, which is a good one to adopt in all tumors that are difficult to reach, of diminishing the size of the tumor, and attempted to divide it in halves by the cautery, but after a few strokes of the knife I approached a pocket of pus, and gave that up for fear of infecting the wound had very little difficulty by taking an eyed probe, threaded with a stout double ligature, in passing the probe through the centre of the pedicle, and then with the double ligature ligating it in halves ligatures controlled the circulation perfectly vessels in the exposed stump were picked up and ligated one by one as a special security was perfect, and the anterior wall of the peritoneum fell easily into place and united by primary intention At the end of a week there was nothing left of this

This case is an important illustration, it seems to The commencement of the in- of considerable size, where the line of incision is It is carried in a The saddest part of my report is to come

cerebral trouble and suppression of urine, and she died with all the symptoms of uremia this afternoon at I o'clock, sixteen days after the operation yet a satisfactory examination has not been made to determine the condition of the opposite kidney, been submitted to examination, but none have shown tubercular bacillus

The post mortem examination showed a highly congested swollen organ in the remaining kidney, the capillary vessels were ruptured in many places

LOCAL MASSAGE FOR LOCAL NEURASTHENIA

Read before the Section for Clinical Medicine, Pathology, and Hygiene, of the Suffolk District Medical Society, November 9, 1887

> BY DOUGLAS GRAHAM, M D. OF DOSTON MASS

Neurasthenia, as I understand it, may be either general or local, affecting the nerves or nerve-cells of all, or any part of the cerebro spinal or sympathetic system Its manifestations are those of exhaustion or too easy exhaustibility of nerve force, and its pathology, malnutrition of the nerve cells, in volved with concomitant instability of their circulation in the form of anemia or hyperemia, or alter It predisposes to, it accompanies, nations of these it results from disease, the nervous shock and the tedious recovery from injuries point to other sources, and it may be caused by overwork, worry or sheer The agreeable fatigue after a satisfactory day's work, that insures sound sleep, may be regarded as a healthy form of neurasthenia, if the Hibernianism may be pardoned

It is a matter of common observation, that those who are compelled to hard manual labor, seldom suffer from nervous prostration, and amongst the more fortunate who may be predisposed to neurasthenia, those who are deeply interested in some hobby or occupation that keeps mind and body active, have found the best means of prophylaxis The same means that serves for its prevention, also supplies us with a clue to one of the most valuable agents that can be employed for its relief in recovery cise keeps the circulation active, but requires effort of brain, spinal cord and nerves, as well as muscles, at a time when our object may be to afford rest to one or all of these parts of an overtaxed nervous Massage supplys this want, and will keep the circulation going with a minimum or no expendiheart, and afford it rest also Nay more, for it is getting to be the fashion not only amongst the laity, but also with some physicians, to say that massage imparts energy to the patient, though I confess I do not exactly understand what this means Certainly, many who submit to massage feel much more vigorous, light, and supple after even the first application than they did before it

ing the equilibrium of their forces, by facilitating the circulation of blood, lymph, and the transmission of nerve-force?

I have previously stated elsewhere that in cerebral exhaustion the relative value of massage was almost neither has there been a satisfactory microscopic | mil, and that out-of door exercise was of paramount examination of the tumor Several sections have importance, but I have since found reason to modify this in favor of more massage and less exercise such cases, massage of the head alone daily, or every other day, is better than applying it all over the patient, unless there be a rare idiosyncrasy that will not allow the head to be manipulated

There are people, not a few, who, when using their brains, suffer from uneasy sensations in the lumbar or dorsal region, and these discomforts continue after the cessation of study, causing wakeful-Generally, there is also some spinal irritation In such cases, massage of the in the region affected back alone will often induce sound sleep, and, next day, the patient feels inspired with faith, hope, and courage, in place of doubt, dread, and fear of meeting appointments With these cases a much more marked effect is produced by local than by general massage, except when the tenderness of the muscles and spinal irritation is extreme, unfitting them for every kind of work, and the massage should be general, omitting the back at the first seances, but gradually approaching it at subsequent ones

In other cases of what may be called local neurasthenia, if the term can be allowed for this purpose, such as writer's cramp, or the cold, small, and feeble muscles resulting from injury, disease, or disuse, massage and exercise, carefully adapted, have given excellent results To these have recently been added another affection, namely, laryngeal cramp of musicians and speakers, for the local treatment of which electricity and massage are considered the most effectual measures

It is not the purpose of this paper to go into the details of applying massage, nor to consider its minute effects, but I think it will be a revelation to many to experience either in their own heads, or to observe in those of their patients, the light, comfortable, delightful feelings that are produced by the resistance of a skilled manipulator to forward, backward, and lateral movements of the head impression is that the interior of the head has been benefited, and the effect is hardly secondary to mas sage, which rather gives the impression that the exterior has been improved

The following cases seem to me sufficiently worthy of notice as examples of the conditions mentioned

Case I—A J, 23 years of age Three years ture of nerve-force from the patient, and deep prior to my being called to him, he had been running massage without friction will lessen the beats of the races at college at the same time that the functions of his brain flagged, and study had become so irksome, producing headache and insomnia, that he gave it up for a year At the end of that time he returned to college for a year, and, to use his own words "patched up and graduated," and for the year before I saw him he had been trying to recuperate by resting at home At this time, even walking But may not this rather be sometimes produced discomfort in his head owing to rousing of their latent energies, and restor- first visit he had been suffering from headache, with tol-

erably acute pains in the external branches of the fifth pair of nerves, and had but little sleep for four The immediate cause of this had been too much conversation with friends on the evening of a holiday Massage of twenty minutes to the head alone, in the evening, almost relieved the headache and neuralgic pains, and was followed by an excellent night's sleep After this massage of the head, with resistive movements to the muscles of the neck, was repeated seventeen times in twenty-four days, and the improvement in sleep, in comfort of the head, and in the power of using his mental faculties was so from headache, which caused him to be out of his great, that it became a serious question whether he should not abandon a six months' sea-voyage that he had engaged Marks of improvement that may be mentioned were, that when he had an occasional wakeful night, he felt no worse on the following day, he had none of his former anxiety in taking charge of massage of the head on three successive days, and his class in Sunday School He attended a large party late one night without any after effects, and he being manipulated, and for a short time afterwards walked about freely, and all while he was preparing for an absence from home of six months or a year Medicine had been laid aside before massage was 1ed in this case

Case 2 —Rev D L, aged 66 years, has a good appetite and is well nourished, weighing about 180 For twelve years, he had suffered much from wakefulness He requires from eight to nine hours of sleep, but seldom got more than five or six hours of broken, unrefreshing slumber At times he would fall asleep soon after retiring, to wake up in a short time, at others, he would lie awake for hours before getting to sleep Besides discomfort about the head, he had still more distressing dull ache and uneasy sensations in the lumbar region, aggravated

by study or wakefulness

He found some relief from giving up his ministerial duties ten years before I saw him He came to me on the 25th of January of this year, and after thirtyfive minutes of massage on his head and back at noon time, he passed the remainder of the day in comfort, and that night and the following had seven hours of sleep each, so that when he came to me on the second day after massage he was hopeful and Massage was repeated at II A M on head and back, with increase of comfort to the patient He did not sleep so well the following night as he did the two preceding nights, but he realized that he was quiet and serene, and feit that he was resting, and next day was refreshed This day he had a re freshing sleep of an hour and a half in the after noon, which he never could obtain before when well, and that night slept steadily for seven or eight hours This patient had massage three times weekly, at or near noon, for seven or eight weeks, and the result of the first week is a fair average of the succeeding Five good nights of sleep out of six, with a nap of an hour or two in the afternoon, and when wakeful, he felt that he was resting, and, the following day, was not miserable from loss of sleep, as before massage, vigor of body and mind gradually increased, and he could take part in lectures, sociables, and other evening entertainments without loss not feeling compelled to do anything Saturdays of sleep, as formerly Mild tonics and stimulants and Sundays were her poorest days, and a vacation

always made this patient worse An epiphora that had troubled him for many years disappeared under massage of the eyelids

Case 3 -Mr E B, 35 years of age, had been in good health for several years, and attended to his business, which involved great detail, from 9 A M to 6 PM, with an hour off at noon for lunch He had remained in the city all the previous summer, and felt very well when he went away for a vacation of several weeks to Colorado, returning on November From the time of his return he began to suffer office several hours daily, and, by the end of three weeks, this became suddenly so much worse that he was obliged to leave his office altogether was a slight elevation of temperature, but still he had a good appetite, and slept well I gave him the headache was relieved only while the head was When massage was being done on the right side of the head, the ache would disappear and increase on the left side, and, on doing both sides they were relieved, and the ache increased in the back of the head, and on masseing the back of the head, the dis comfort would disappear from there and increase in the forehead, and, on manipulating this region, it would disappear altogether for a time. In other cases, I have chased pain in this way all over the patients without being able to dislodge it completely, only temporary relief being afforded at the place of

application

Case 4, will serve to show still farther that it is not always well for those who are inclined to nervous exhaustion to give up their employment when working easily, and go away on a vacation Miss M P, 34 years of age, teacher in a High School, had been subject to headaches all her life Her parents had highly nervous temperaments One year before I first saw her, the headache had been so severe that she was confined to her bed for seven days with pains all over her, and elevated temperature, and since then, the headaches have been more frequent and more severe than before, and usually accompanied with nausea and vomiting Evidently the case was one of migraine The ache was on the left side of the head, in the left eye, and more especially over the left tempero parietal region, accompanied with a crawling sensation at the back of the head, and soreness of the muscles of the back of the neck The left side of the face was smaller than the right She had great weariness and weakness in her aims, so that it tired her even to raise them cervical and upper dorsal region, there was much tenderness on pressure over the spinous processes Her appetite was good, bowels regular, and she slept Notwithstanding the increase in frequency and severity of headaches for a year, she had gained in weight, mainly adipose, so that she weighed 160 pounds, her ordinary weight being 123 pounds She continued her duties as a teacher, and found that she felt better when occupied in this way than when

of two months in the South ten months before she a very short distance at a time came to me was of no apparent benefit to her, but, she thought, made it all the harder for her to begin her professional duties again Correcting examination papers fatigued her more than anything else She could walk three or four miles with case

The first massage of thirty minutes on the head alone left this region "perfectly comfortable" until the second massage was repeated, two days later, when this comfort was extended to the manipulated regions-head, neck, arms, and shoulders-and a burning sensation between the shoulders was also In four weeks, a continual wooden, numb sensation of the left side of the head was not only relieved temporarily, but did not return, and, cor responding objectively to this, her tough, indurated scalp had become soft and supple Sixteen days after she came to me she could not stand, and had an account of weak and uneasy sensations in the back of her neck, as if her head would drop back wards when she attempted to hold the book, but she could sit and read with case This was at the catamenial period, when she was generally worse in But, two days later, she was much sur every way prised to find that she had recuperated more quickly, and to a greater extent, than ever before This patient had massage twenty five times in ten weeks, with increasing improvement, and this continued after treatment was omitted, so that she was practic ally well-sufficiently well to enjoy her summer vacation, which helped to confirm the benefit previously received Six months later, she reported that she had continued quite well The following spring her troubles returned in the same way, but less severely than formerly They were speedily re moved by massage, and stayed away for a year, when, again, there was a slight relapse, and more speedy recovery under massage At times, she had found nux vomica more beneficial than any other internal remedy, but even this had lost its effect before massage was tried

Case 5 -Mr J B, aged 33 years, has always been a nervous man He often felt fatigue in the lumbar region, but this he regarded as a matter of course, and he was always capable at business until six years before I first saw him At that time he was in an elevator which was being tested against sudden falling by means of some "suie patent preventive" The experiment failed, and the elevator fell eighty feet with six men in it While descending, our patient sat as tailors do, hoping thereby to diminish the shock of stopping He got out apparently none the worse, walked four squares to his newspaper office, for he was then an editor, and dictated an ac count of the accident He stayed at home for five or six weeks, but was not confined to bed After evening, the region of the spine was painful, but rehef was often found by pouring cold water upon it, at other times, from very warm water During va cation he was perfectly well, and played lawn tennis

Conversation and reading quickly tired him, and part of either would escape his attention A few hours at business would cruse nrusea and headache, and make him feel generally used up Appetite, bowels, and sleep normal

At my first interview there was much tenderness on pressure over the spinous processes and muscles of the back, but, after three massages in nine days, they could be manipulated quite vigorously six massages in eighteen days, he was practically as well as ever Manipulation was exceedingly agreeable to this patient, and, while it was being done on either leg or hip, the agreeable sensation was felt in the back and in the other leg and hip, as well as at the seat of application About once a year, usually in the fall, after his vacation, this patient finds himself used up, as just described, and he has learned by experience to rely on the prompt relief afforded by massage He has also found wine of coca of some I have frequently made similar cases worse by using massage too vigorously to begin with

Case 6 - When Mrs M W came to me in October, 1884, she was 58 years of age, and weighed 213 1/2 pounds Her adipose tissue was supple and of good consistency She had then been suffering for three years from a continual, distressing feeling of weakness in the right leg and thigh, which first made its appearance when there was some enlargement of the internal saphenous vein, but this had long ago dis-On examination, the whole limb seemed normal in every respect. The patient was not at all of a nervous, hysterical, or imaginative temperament, having been at the bombardment of Fort Sumpter, once in a steamboat explosion, and once made a long voyage in a vessel with the cargo shifted, so that there was imminent danger of the vessel upsetting, besides having travelled twice around the world

A walk of a square was as far as the patient could go with comfort, and a walk of one fourth of a mile caused great fatigue and increased the feeling of weakness She had tried absolute rest for one, two, and three months at a time, during which she lost flesh, but the limb did not improve At my request, she omitted potatoes, sugar and butter from her diet and began walking for two minutes every hour during the day, which was increased daily one minute Massage was given to the leg, thigh, every hour and hip three times weekly The first time it comforted and rested the limb, and after this passive and resistive movements were also given, which at first tired the limb, but this was at once counteracted by manipulations At the end of two weeks she could walk half a mile without fatigue—twice as far as she could before with great fatigue-and a distressing pain that previously came after slight exertion at the exit of the sciatic nerve had not been felt for a week this he resumed his duties, but it was eight months At the expiration of four weeks the patient walked before he could walk a mile For a long time in the a mile and a half with ease, feeling but slight general fatigue thereafter, and the limb that had been weak was not so tired as the other It was by her own wish that massage was repeated occasionally for a few weeks longer, and she has continued well ever For three weeks before I saw him he had suffered since Under the restricted diet she lost 7½ pounds, from pain in his back and legs, and could walk but and no doubt but this aided her recovery

erably acute pains in the external branches of the always made this patient worse fifth pair of nerves, and had but little sleep for four had troubled him for many years disappeared under The immediate cause of this had been too much conversation with friends on the evening of a Massage of twenty minutes to the head alone, in the evening, almost relieved the headache and neuralgic pains, and was followed by an excellent After this massage of the head, with night's sleep resistive movements to the muscles of the neck, was repeated seventeen times in twenty four days, and the improvement in sleep, in comfort of the head, and in the power of using his mental faculties was so great, that it became a serious question whether he should not abandon a six months' sea-voyage that he had engaged Marks of improvement that may be mentioned were, that when he had an occasional wakeful night, he felt no worse on the following day, he had none of his former anxiety in taking charge of his class in Sunday School He attended a large party late one night without any after-effects, and he walked about freely, and all while he was preparing for an absence from home of six months or a year Medicine had been laid aside before massage was in this case

Case 2—Rev D L, aged 66 years, has a good appetite and is well nourished, weighing about 180 For twelve years, he had suffered much from wakefulness He requires from eight to nine hours of sleep, but seldom got more than five or six At times he hours of broken, unrefreshing slumber would fall asleep soon after retiring, to wake up in a short time, at others, he would lie awake for hours before getting to sleep Besides discomfort about the head, he had still more distressing dull ache and uneasy sensations in the lumbar region, aggravated

by study or wakefulness

He found some relief from giving up his ministerial duties ten years before I saw him He came to me on the 25th of January of this year, and after thirtyfive minutes of massage on his head and back at noon time, he passed the remainder of the day in comfort, and that night and the following had seven hours of sleep each, so that when he came to me on the second day after massage he was hopeful and Massage was repeated at II A M on head and back, with increase of comfort to the patient He did not sleep so well the following night as he did the two preceding nights, but he realized that he was quiet and serene, and feit that he was resting, and next day was refreshed This day he had a re freshing sleep of an hour and a half in the after noon, which he never could obtain before when well, and that night slept steadily for seven or eight hours This patient had massage three times weekly, at or near noon, for seven or eight weeks, and the result of the first week is a fair average of the succeeding Five good nights of sleep out of six, with a nap of an hour or two in the afternoon, and when wakeful, he felt that he was resting, and, the following day, was not miserable from loss of sleep, as before massage, vigor of body and mind gradually increased, and he could take part in lectures, sociables, and other evening entertainments without loss not feeling compelled to do anything Saturdays of sleep, as formerly Mild tonics and stimulants and Sundays were her poorest days, and a vacation

An epiphora that massage of the eyelids

Case 3—Mr E B, 35 years of age, had been in good health for several years, and attended to his business, which involved great detail, from 9 A M to 6 PM, with an hour off at noon for lunch remained in the city all the previous summer, and felt very well when he went away for a vacation of several weeks to Colorado, returning on November From the time of his return he began to suffer from headache, which caused him to be out of his office several hours daily, and, by the end of three weeks, this became suddenly so much worse that he was obliged to leave his office altogether was a slight elevation of temperature, but still he had a good appetite, and slept well I gave him massage of the head on three successive days, and the headache was relieved only while the head was being manipulated, and for a short time afterwards When massage was being done on the right side of the head, the ache would disappear and increase on the left side, and, on doing both sides they were relieved, and the ache increased in the back of the head, and on masseing the back of the head, the dis comfort would disappear from there and increase in the forehead, and, on manipulating this region, it would disappear altogether for a time cases, I have chased pain in this way all over the patients without being able to dislodge it completely, only temporary relief being afforded at the place of

application Case 4, will serve to show still farther that it is not always well for those who are inclined to nervous exhaustion to give up their employment when working easily, and go away on a vacation Miss M P. 34 years of age, teacher in a High School, had been subject to headaches all her life Her parents had highly nervous temperaments One year before I first saw her, the headache had been so severe that she was confined to her bed for seven days with pains all over her, and elevated temperature, and since then, the headaches have been more frequent and more severe than before, and usually accompanied with nausea and vomiting Evidently the case was The ache was on the left side of one of migraine the head, in the left eye, and more especially over the left tempero parietal region, accompanied with a crawling sensation at the back of the head, and soreness of the muscles of the back of the neck The left side of the face was smaller than the right She had great weariness and weakness in her aims, so that it tired her even to raise them cervical and upper dorsal region, there was much tenderness on pressure over the spinous processes Her appetite was good, bowels regular, and she slept Notwithstanding the increase in frequency and severity of headaches for a year, she had gained in weight, mainly adipose, so that she weighed 160 pounds, her ordinary weight being 123 pounds continued her duties as a teacher, and found that

she felt better when occupied in this way than when

muscles, restoring natural sensation and motion, massage may succeed when other means have failed

9 Deep massage without friction has proved of it is well marked more value in my hands than all other forms of mas sage put together, in the cases herein considered

10 Massage can be overdone, producing opposite

effects from a moderate application

11 Besides massage, carefully graded exercises at regular times, are valuable accessories in the restoration of motion

12 Massage is not the only means of treatment for neurasthenia. Its selection is usually decided upon after the failure or exhaustion of every other means, in the same manner that the shrewd old divine decided that it was not wise to let the devil have all the good times to himself

MEDICAL PROGRESS.

NERVOUS ORIGIN OF RHEUMATOID ARTHRITIS -At the meeting of the Royal Medical and Chirurgical Society, on November 22, DR ARCHIBALD E GAR ROD read a paper on this subject, of which the follow Some of the arguments which ing is an abstract have been put forward in support of the view that rheumatoid arthritis is a disease of nervous origin, are examined in the light of a large number of cases The statistics given are based upon a series of 500 Arguments are adduced in support of the following propositions 1 That the causes of rheumatoid arthritis are such as might be expected to act upon the central nervous system 2 That the distribution of the lesions is such as would be likely to result from nervous lesions 3 That the distribution of the lesions is similar to that of certain arthropathies of spinal origin. The influence of heredity is first discussed In 216 cases out of 500, there was a family history of joint disease, sometimes of more than one variety There was a history of gout in 86, of probable gout in 10, of rheumatism in 64, and of other conditions which may be classed together as probably rheumatoid arthritis in 84 These figures can only approximate to accuracy as they are based upon information given by the patients The influence of uterine causes is next discussed, and it is shown that when the female cases are arranged according to the age of the patients when the disease commenced, there is a steady increase in numbers up to the period of the menopause and a steady decrease after that Amongst the male cases there is no such regularity Of the 500 patients 411 were women, and only 89 men The influence of anxiety and care, mental shock, injuries, damp, cold, and previ ous rheumatic attacks, are discussed, and each of these is shown to have a share in the causation of Stress is laid upon the extreme sym and some examples are adduced given for believing that there is a tendency for the tures, sutures and dressings

8 For improving the nutrition of nerves and joint lesions to advance up the limbs from the periphery towards the trunk This order of invasion is by no means constant, but in particular instances In the localized form of the dis ease, it is, of course, absent The knees rank only second to the hands in liability to rheumatoid arthritis Lastly, it is shown that there is a close resemblance between the distribution of the joint lesions in rheumatoid arthritis and in the recorded cases of arthritis following spinal concussion, whereas in more local spinal injuries one or more large joints are usually affected, as in tabes dorsalis sociated nervous phenomena, such as muscular wasting, increase of tendon reflexes, etc, are regarded as secondary to the joint lesions, and as therefore lending no efficient support to the theory of the nervous origin of rheumatoid arthritis Dice Duckworth agreed with the views expressed in the paper The morbid anatomy of this disease required very much more investigation than had at DR ORD had been interested present been given in this subject for many years The joint troubles were to be regarded rather as symptoms than as the whole disease He came to the conclusion that nervous influences had a great deal to do in the causation of this disease He believed that nervous influence was reflected from the uterine organs to the spinal cord and on to the joints also exerted a primary influence Injury might lead to a joint affection, and then the nervous system tended to propagate the joint change to other joints He compared rheumatoid arthritis to progressive muscular atrophy In a case of chronic cervical pachymeningitis there was much muscular and cutaneous wasting, and later a remarkable degree of chronic osteo arthritis developed In another case of spinal injury joint trouble followed at a long interval the muscular wasting DR Buzzard said that in association with Charcot's disease of the joints there was a much clearer evidence of disease in the central nervous system than was the case in rheumatoid arthritis He alluded to the various crises and paroxysmal secretions occurring in tabes dorsalis as evidence of the involvement of the central nervous in most cases Eight years ago he promulgated the theory of a joint centre in the medulla oblongata, and he brought forward arguments to show that acute rheumatism might be an acute affection of the medulla oblongata DR HERRINGHAM alluded to the belief which he shared that cold and damp were very potent causes of rheumatism and rheumatoid arthritis DR GARROD, in reply, said that he should have classed Dr Ord's case of myotrophy as one in which the arthropathy was due to definite nervous lessons, and therefore not of the same category as rheumatoid arthritis - Lancet, Nov 26, 1887

PLASTIC SURGERY --- MR C B KEETIEY says It will be granted that all parts of the body are susceptible to septic inoculation, therefore one of the first rules of plastic surgery should be Thoroughly metry of the joint lesions in rheumatoid arthritis, disinfect the parts to be operated on, the hands of sur-Reasons are geon, assistant and nur se, the instrument, sponges, liga-

Case 7 —Miss E H was 39 years of age when I attended her in the winter of 1883-84 She is irregularly astigmatic, and suffers from headache, and this ing the last eight or ten days of treatment, it became is worse at the menstrual period, which recurs every three weeks and a half, accompanied with pain She suffers much at times from indigestion. She is a lady with a strong mind, a clear intellect, an unwearied conversationalist, and, in the language of her physi cian, who sent her to me, "she is a preeminently hyperæsthetic subject, and would be hysterical, did not mous and digestion good the brain govern the cerebium abdominale" For five years she has suffered with a pain in her right knee, impairing locomotion, and the latter part of this rightly, that massage had given her a start, and imtime there was pain also in the outer and posterior aspects of the thigh, where the muscles were considerably atrophied—so much so that her other discomforts seemed small in comparison with those of the well, there are few, if any, who have not some weak The trouble in the limb came when she was run down from nursing a sick relative, and coincident with this a severe cough that had been increasing every winter disappeared, and did not return ing these five years under rest, with and without fixed at 2 PM, and another half-an-hour's massage on same dressings, changes to country and seashore, the use of tonics and sedatives interally and blisters externally, there would be sometimes a little improvement in the knee, but always followed by speedy relapse on slight or no provocation, such as accidentally hitting it against something, or being obliged to use it a little more than usual. At times the pain was relieved by walking, at others made worse. It was aggravated by cold weather and by riding in a carriage

Examination showed that the affected limb was much smaller than the other, the skin cold and dry, the muscles atrophied, but there was nothing especially noticeable about the knee, save slight puffiness and great tenderness on pressure upon the internal Owing to pain and weakcondyle, not in the skin ness, which were aggravated by walking, she could take but a few steps when massage was begun, and the only symptom then in her favor was steady sleep Massage was applied three times a week for eleven weeks and a half, being omitted for a few days at one time on account of unusual pain in back, stomach For the first four weeks, massage, and intestines with gradually increasing exercises, was confined to the affected limb, with the result that she was at the end of this time taking four walks daily of ten minutes each, besides exercises of standing on tip toe, stepping up two steps at once, holding the limb out extended, and elevating it sideways when lyirg down From the first the skin became warmer, softer and suppler, and the muscles fuller, as shown by an in crease of one-half inch around the calf, one fourth inch at the knee, one-eighth inch three inches above the patella, and one fourth inch seven inches above may not be restless nor feel the loss of sleep on the the patella When treatment was discontinued these following day gains were one-half inch, five eighths, three-eighths, and seven-sixteenths, respectively But at the end | massage of four weeks the pain was still about the same, notwithstanding the improvement in locomotion, nor had it entirely disappeared when massage was given up

As soon as she made known the heart and abdominal troubles, massage was applied for ten minutes to massage, improvement may yet go on after massage each of these regions also, which was during the last has been discontinued

seven weeks of treatment Headache was improved, sleep became more refreshing, digestion easier Durevident that, though the patient was much better, and could go about much more freely on foot and in a carriage, she had come to a stand-still, and consequently the treatment was terminated rather sooner than she wished A year later I saw her and she was the picture of health Her appetite was enor-She had gained many pounds in weight and could walk freely, but still suffered from headache She considered, and I think provement had continued since it was omitted, for no other treatment had been used

Amongst people who may be considered perfectly When fatigued or worned I suffer from tension and dull ache throughout my whole right side In September, 1884, when in Paris, I had one man give me half-an-hour's massage on my right side only, The manipulation was slight, superside at 5 P M ficial and rapid and at the time of its being done seemed very meffectual But that night I never slept so sound in a railroad train in all my life, as I did from Paris to Calais, and while crossing the channel I was not even sick Two days later I played deck quoits all one afternoon when the thermometer was 80° in the shade and the ship rolling. Next morning my playmates could scarcely get out of their berths, they were so stiff and tired, and so was I, but the fatigue was all confined to my left side and not to the right as formerly

It may be said that these were not very sick people, but they are cases that prove troublesome to physicians, and they were certainly in conditions which any one of us would gladly be freed from is not necessary that I should dwell upon extreme cases of nervous prostration that have been treated by absolute rest, forced feeding, massage and elec-I could give further details of the other mentioned cases and also of similar ones which would seem to justify the following conclusions

That massage induces sleep

That even when massage is applied in the forenoon its soporific effects may not disappear before bedtime, though in general the later in the day massage is used, for promoting sleep the better

3 Disagreeable feelings of drowsiness and languor do not necessarily intervene between massage in the Aptitude for forenoon and sound sleep at bedtime rest or work generally follows massage

4 When people are wakeful after massage they

5 Spinal irritation is relieved or disappears under

6 For local neurasthenia there is no need of general massage, unless the whole system be secondarily ınfluenced

7 When affections have come to a stand-still under

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, No 65 RANDOLFII STREET,

CHICAGO, ILLINOIS

SATURDAY, JANUARY 7, 1888

MEDICAL LEGISLATION

In continuing the discussion of this subject from page 815 of The Journal for December 24, 1887, we cannot express more concisely our views regard ing the proper standard of medical education that should be required for a license to practice medicine, than by quoting the third section of the law now in force in Minnesota, with the interpolation or addi tion of two or three lines enclosed in brackets, as "Sec 3 All persons hereafter commencing the practice of medicine and surgery in any of its branches in this State, shall apply to said Board for a license so to do, and such applicant, at the time and place designated by said Board, or at a regular meeting of said Board, shall submit to an examination in the following branches, to wit Anatomy, physiology, chemistry, histology, materia medica, therapeutics, preventive medicine, practice of medicine, surgery, obstetrics, diseases of women and children, diseases of the nervous system, diseases of the eye and ear, medical jurisprudence, and such other branches as the Board may deem advisable, and present evidence [of having studied medicine three years, including] attendance on three courses of lectures of at least six months each, [and two courses of clinical instruction in a general hospital containing an average of not less than fifty patients], said Board shall cause such examination to be both ser entific and practical, but of sufficient seventy to test the candidate's fitness to practice medicine and sur-When desirable said examination shall be conducted in the presence of the Dean of any med

of this State After examination said Board shall grant a license to such applicant to practice medicine and surgery in the State of Minnesota, which said license can only be granted by the consent of not less than seven [of the nine] members of said Board, and which said license shall be signed by the President and Secretary of said Board and attested by the seal thereof. The fee for such examination shall be the sum of \$10, and shall be paid by the applicant to the Treasurer of said Board, to be applied by said Board towards defraying the expenses thereof—and such Board may refuse or revoke a license for unprofessional, dishonorable or immoral conduct."

With such a standard of preliminary general education for the medical student as we suggested in THE JOURNAL of December 24, 1887, and the foregoing section of the Minnesota law with the amendments in brackets, enforced by a competent and impartial State Board of Examiners, in each State, there would speedily follow a marked improvement in the educational status of the profession, and a corresponding diminution in the number of both medical students and medical schools But the actual permanent benefits to be obtained from the creation of such legal standards of education for the medical profession will depend very much upon the competency and faithfulness of the several State Examining Boards Consequently the questions, by whom shall such Boards be appointed, what shall be the qualifications necessary to render any person eligible for appointment on such Boards, and to whom shall the members of such Boards be responsible for the proper performance of their official duties? present more difficulties in arriving at satisfactory answers than in adjusting any other details connected with medical legislation We will therefore reserve a more full discussion of these questions until next week

THE NEXT MEETING OF THE ASSOCIATION

Four short months intervene between the present and the time for the next meeting of the American Medical Association. While the steady growth of the Association promises success for its future, the necessity is as imperative as ever that the officers and members should cooperate each year to make the annual meetings as successful as is possible from a scientific standpoint, and as harmonious and pleasureable as possible from a social standpoint.

conducted in the presence of the Dean of any medical school or the President of any medical society

The number of papers has greatly increased during the last few years, and especially since The local school or the President of any medical society

JOURNAL was founded

In many Sections more are

offered than can be read While, therefore, there is no dearth of material, experience has demonstrated that the value of the papers presented to the Sections depends chiefly upon the thoroughness with which their officers canvass the best authors and observers for contributions following heads, vizing the following heads, vizing the stablish positively in the results of real values of the results of well discovered by the results of well discovered by the facts on any

Since the number of papers are annually increasing all that contemplate presenting contributions should study to make them concise and to the point The following rule of the Association must be borne in mind "No paper shall be read before either of the Sections, the reading of which occupies more than twenty minutes" Longer papers may be read It must also be remembered that "it shall be the duty of any member of the Association who proposes to present a paper or report to any one of the Sections to forward either the paper or a title indicative of its contents and its length to the Chairman of the Committee of Arrangements at least one month before the annual meeting at which the paper or report is to be read " And further "It shall be the duty of the Chairman and Secretary of each Section to communicate the same information to the Chairman of the Committee of Arrangements concerning such papers and reports as may come into their possession"

Regard for these rules is necessary in order to give the Chairman of the Committee of Arrangements time to prepare the annual programme, to arrange the order in which papers are to be read, and to have the programmes printed for distribution at the beginning of the meeting. In times past papers have been crowded upon the programme during the month preceding the meeting, but many are annually disappointed because they send their papers too late

The next meeting will be held in Cincinnati, and will begin on the second Tuesday of May We can safely prophesy an unusually large and successful meeting, for the central location of Cincinnati will make it easy of access from all directions. The city itself offers many attractions to strangers and the Committee of Arrangements, with its able Chairman, Dr. W. W. Dawson, of that city, will make every possible arrangement for the comfort and pleasure of the members in attendance.

We would also call attention to the following rule of the Association regarding papers to be read in the Sections

Resolved, That the several Sections of this Association be requested, in the future, to refer no papers or reports to the Committee of Publication, except such as can be fairly classed under one of the three between 5000 and 6000 ohms

following heads, viz 1st Such as may contain and establish positively new facts, modes of practice, or principles of real value 2d Such as may contain the results of well devised, original experimental researches 3d Such as present so complete a review of the facts on any particular subject as to enable the writer to deduce therefrom legitimate conclusions of importance (Transactions, Vol 16, p 40)

Members are also requested to note the fact that the Committee of Publication is vested with discretionary power in the preparation and publication of the matter referred to it by the Sections for publication

ELECTRICAL RESISTANCE IN THE HUMAN BODY UNDER PATHOLOGICAL CONDITIONS

That the body offers considerable resistance to the passage of electrical currents is well known. And that much variation in this resistance exists in different individuals, and even in the same person at different times, was long ago demonstrated. This variability is known to be due in part to the use of currents of different strength, of electrodes of different sizes, to variations in the moisture or dryness of the skin, to the thickness of the skin, to the distance apart of the electrodes, etc. In making comparisons of the resistance in many persons much care must be taken to eliminate these various sources of error

Very few observations upon persons in a pathological condition made with accuracy have been re-A year ago Charcot called attention to the corded fact that electrical resistance in the body was constantly lessened in Grave's disease and in certain cardiac affections, notably asystolism, (Gaz des These observations of Hospiteax, 13-15, 1886) Charcot have led R Norris Wolfenden (The Practitioner December, 1887) to make most careful investigations of the same kind upon Grave's disease and less extensively upon others To eliminate sources of error he used uniformly the same electrodes, placed upon the same part of the body in each case, te, on the nape of the neck and on the He tested with the resistance top of the sternum coil his current so that he had one of uniform meas-In this way he tested the resistance in ured strength fifty healthy persons and found it between 4000 and 5000 ohms with a current of 15 volts cases of undoubted Grave's disease he found this resistance to vary between 500 and 1500 ohms This fully coreight of these it was 1000 or less roberates Charcot's observations In ordinary goitre the resistance is not lessened, but was found to vary

In one case of malignant disease of the thryoid it was found to be 8000 In some cases of hemiplegia it varied from 1300 to 4000, in the same number of cases of epilepsy from 1000 to 4000, in three cases of cerebral softening it was 3000, in two cases of paraplegia it averaged 3000, in one case of gen eral paralysis 6500, in one case of infantile paralysis 2600, in a case of hystero-epilepsy 1600 ohms, and in one case of chorea in an adult it Dr Wolfenden further noticed that a current of only two or three volts would in Grave's dis ease produce marked deflection of the galvonom eter needle, with such a current no deflection would occur in health The bodily resistance is therefore almost nothing in this disease Dr Wolfenden can offer no explanation of these changes

FOOD ADULTERATION IN ENGLAND -MR C E Cassal, the public analyst for Kensington, reports that of 499 samples analyzed under the "Food and Drugs Act" 28 per cent were adulterated, and 17 per cent of inferior quality, the greater part of the adul terated or inferior samples being specimens of milk The largest proportion of adulterated samples was from the Sunday milk, only 34 per cent of the sam ples being genuine The amount of fines for all this adulteration was only £37, knowing which one does not wonder at the extent of the adulterations

J K BARTLETT, M D, long well known to the profession as one of the oldest and most respected members of the profession in Milwaukee, Wis, has removed from that city, and taken his residence permanently in Berkeley, Cal His many friends and correspondents should make note of this fact The change of residence at this period of life was caused by the hope of benefiting the health of his family

SOCIETY PROCEEDINGS

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, November 9, 1887

The President, J Solis Cohen, M D, in the

DR DEFOREST WILLARD read a paper on FOREIGN BODIES IN THE URETHRA AND BIADDER REMOVAL BY LITHOLAPALY EVACUATOR WITH LARGE, STRAIGHT, OPEN ENDED CANULA

bodies, the surgeon has to meet with a large amount itself. The forceps can be manipulated through its

of deception upon the part of the patient, when the object has been self introduced, and it is often impossible to obtain any reliable information either as to the presence of the foreign mass or as to its conformation In broken bougies the surgeon should, if possible, have the other remaining fragment in his hand for measurement, or else secure one of similar Any object of peculiar shape should be accurately described, or duplicated It must be remembered, that while a patient may confess to the introduction of but one body, there may be several The position in the canal must be thoroughly fixed In the ante scrotal region this is easily accomplished, and with the aid of a sound and a finger introduced into the rectum even the posterior urethra can be well examined, provided inflammation be not too severe When possible, no manipulations should be attempted for extraction without the body being firmly secured from further recedence Ether is of the greatest value, but cocaine injections may answer for urethral work

Treatment — About one tenth of inserted foreign bodies will be spontaneously expelled, but when the vis a tergo of the urine fails to wash out either a calculus or an object inserted through the meatus, the safest and surest plan is to attach to an ordinary litholapavy evacuator (Bigelow's or other improved pattern) a large, straight tube, which is open at both It contains a movable stylet for ease of introduction The size should be the largest that the urethra will possibly admit (after nicking the meatus, if necessary), say French No 29 or 30, American, No 19, English, No 16, for adults, children in proportion The possibility of the passage of the body through the tube should be determined, if possible, by actual trial, provided a similar piece can be ob-Rarely will any bougie larger than the above-named size be found in the bladder or urethra The method has been so satisfactory in my hands, as is proven by the collection of objects before you, that I always resort to it with confidence, to the exclusion of all other primary devices

If lodgement has occurred in the urethra, the canal must be firmly closed by finger pressure behind the object, while the metallic tube is slid down and carefully caused to engage the catheter or other mass within its calibre, when the bulb of the instrument is slowly compressed until the water has distended the urethra to its fullest limit, thus liberating the body, when suction is suddenly applied while the penis is stretched forward Urless the mass be firmly caught and imbedded in a pocket, this manœuvre rarely fails after a few trials The quantity of water that can be contained in the urethra is so small that the body may require two or three efforts to withdraw it the whole length of the instru-The water should be injected very slowly, but the suction current must be made forcibly spection of the rubber tube can be made through the upper opening without detachment of the cathe-Avoid employing forceps until unsuccessful with the above method, but when necessary to be Unfortunately for the safe extraction of these used, the superiority of the canula again asserts calibre, and if the object be compressible enough to pass the bore, withdrawal can be accomplished without the slightest injury to the mucous membrane Objects of larger size than this tube can seldom be withdrawn with safety by any method save cutting Hairpins can be compressed through the walls of the urethra, and their points passed into the calibre, when they can be completely pushed within the bore and easily withdrawn Beads, peas, pebbles, etc., will easily enter the canula by suction Catheters, wires, etc, will usually require the assistance of Barbed heads of grain can also be ensheathed and withdrawn by this device

evacuator becomes an even more essential aid straight instrument is not always easy of introduc- water tion, but the security gained against subsequent be located and the urethra closed, a large injection urethral injury abundantly repays for the trouble If a flexible or spirally cut obturator is used, the introduction is rendered much easier used first as a sound to discover the offending body, when the bulb of the evacuator is first slowly compressed, so as not to disturb the fragment Suction should always be made quickly, so as to draw the the spoon of the ordinary pocket-case can often be body with force with more energy, so as to move the fragment into better line with the calibre, suction being again rapidly applied. If the body is rounded, and of size that can pass the bore, it will in a few moments be found in the bulb If very long, like a catheter, or pencil, or wire, the chances are not so good that it can be brought into line with the calibre of the As a bougie ordinarily breaks at or near the eye, however, its passage is more than probable Failing, after ten minutes of gentle trial, a lithotrite should be introduced if the body is a bougie or pencil, and is capable of being cut or pinched in two, and the division made. If the bougie is old and brittle, as is presumptively the case, such division with a lithotrite is easily accomplished The segments can then be sucked out, and their total length carefully compared with the remaining portion or Every particle must be secured, lest it lost body form the nucleus of a future calculus Even the broken jaw of a lithotrite might be drawn into the lithotrite of Reliquet, as incision is infinitely safer If the surgeon has not the straight tube with open end, which I advise, he may use the ordinary straight evacuating tube

Necessarily only a small proportion of introduced objects can be removed per urethram, and I should lay it down as a rule, that any foreign body too large to pass the calibre of this No 29 tube, unless it be dicate the location of the obstruction and of the tube very soft and pliable, should be removed by lithotomy, either perineal or suprapubic Great care must dangers, but laceration is worse be exercised in the search, if the object be sharp-The inflation pointed, lest a perforation be made of the rectum, if epicystotomy be done, in order to lift the bladder, must be dispensed with if the object rest by its splint action The upper route gives more room, is sharp-pointed and while there is a slight risk of wounding the peri- lodged behind it, dilatation or free external incision toneum, yet we must remember also, in the extrac- of the stricture should be practised tion of large objects, as well as calculi, by the permeal route, that the rectovesical fold of the peri- from the urethra, the point can sometimes be im-

toneum is in close proximity to the neck of the bladder, and may not escape involvement in the subsequent inflammatory action

If the walls of the bladder were only of sufficient strength to warrant their immediate sewing with catgut or silk, and permit primary union under strictly antiseptic dressings, while the urine were drained off below, the suprapubic route would cer tainly be decidedly the better one, but for the present, we must be content to drain the suprapubic

In the absence of an evacuator, the expulsive force of the urine is often sufficient to dislodge a urethral If the object has passed into the bladder, the impaction, especially if the meatus is closed for a moment, so as to obtain the full dilating power of the Failing in this effort, if the foreign body can of sweet oil may be thrown in, after a hot bath, and the largest possible bougie carried down to the body The tube is to stretch the membrane, while pressure from behind is made either by the surgeon's finger or by the ex

pulsive efforts of the patient's bladder

Should lodgement be made in the fossa navicularis, Failing, the water is next ejected hooked behind the object and assist in coaving it A hairpin, or wire doubled upon itself and slightly bent, or a blunt curette, makes also a valuable extractor An excellent instrument also is the articulated scoop of Leroy d'Etiolles, which, being introduced past the foreign body, has a mechanism by which its tip is then bent at right angles to the shaft, and is capable of making strong but dangerous traction The abruptly short-beaked sound that I always use for sounding the bas fond of the bladder, can sometimes also be "wormed" past the obstruc tion, and effect its dislodgement Long urethral forceps are of great service, as they serve partially to protect the canal during extraction, but they do so far less effectually than does the straight tube be fore described, which should be placed in every evacuating set Hunter's or Civiale's three bladed forceps are occasionally used, but I always look with abhorrence upon dragging any object forcibly through A dangerous instrument is the urethral the canal for all rough and large bodies When the substance lies posterior to the triangular ligament, gentle attempts should be made to push it into the bladder, only after the evacuator has failed to dislodge it necessary to operate, the raphe should be closely followed, while a large staff is held in position to in-

> An incision in front of the scrotum is easily made, Lithotomy has its and should be closed after the removal of the body Treated antiseptically, by catgut or quilled sutures and with either a retained catheter, or with frequent catheterizations, immediate union may be confidently The quilled suture gives more perfect expected

If a stricture exists, and the foreign body is

For the removal of pin, bonnet pins, or needles,

and by sharply bending the penis, the head after reversal drawn through the tube by suction or by forceps It is seldom necessary to cut the pin when this method is used lost from a porte caustique, the evacuator, charged in cutting short the course of the disease with salt water, should be at once used if the force urmation does not expel the mass devices have been practised in the absence of instruments, to rid the urethra of impacted bodies, but the knife is far safer than rough instrumentation. In the absence of the straight evacuating tube, an extra sized catheter, with open end, and a large syringe, might prove useful

Blood clots in the bladder are practically foreign bodies, and are best removed by gentle suction through the curved evacuator, or through the blood catheter, which I here show, the large eye of which is closed down during introduction by a spirally cut

Catheter accidents are so frequent that instru ments should be often examined Only recently I found that the distal extremity of my much used pocket case instrument could be slipped from its screw thread by a very small amount of traction Old gum bougies should be thrown away as soon as vous system by the use of sedatives and tonics they begin to lose their elasticity

To summarize

- The litholapaxy evacuating tube, large, straight, and with open end, is the surest and safest instru ment for the removal of foreign bodies from either urethra or bladder
- to break up all bodies capable of division
- tear of the neck of the viscus or of the canal
- 4 The suprapubic and median perineal are the safest routes of entrance to the bladder when suc tion fails
- Forceps should be used with the greatest care, and always through a straight tube, which insures protection both to the urethra and neck of the bladder during both exploration and extraction

CHICAGO MEDICAL SOCIETY

Stated Meeting, November 7, 1887 THE PRESIDENT, W T BELFIELD, M D, IN THE CHAIR

Dr J A Robison read a paper on

THE TREATMENT OF PERTUSSIS

He said that since the discovery by Poulet in 1867 of a parasite which is probably the cause of whoop ing cough, the disease has been treated by the local application of such germicidal agents as carbolic acid,

bedded in a way or gum bougie, but it is easier is difficult to get children to allow the administration washed out with the evacuator If immovable, the of the drugs, but he had used with success a solupoint can be pushed through the walls of the urethra, tion of cocaine and resorcin in Semple's Atomizing Inhaler, the vapor being so fine that the drug is inhaled into the bronchial tubes without producing any laryngeal spasm This method of treatment had If a piece of nitrite of silver is been successful not only in relieving the cough, but

Whooping cough is a dis-DR F E WANHAM Many ingenious case for which a great many specifics have been advocated, but I really believe that we possess none Something over a year ago I remember reading of the fumes of sulphur as being a specific, coming from a high authority, I thought that we had at last found a remedy for this disease, but upon giving it a faithful trial I found it entirely useless, the patients manifesting no relief whatever And the same may be said of a great many other remedies that have been advocated as specifics As it is generally conceded that the disease is produced by bacilli found in the mucus of the throat, the larynx and the trachea, and that the peculiar cough is reflex in character, it certainly follows that there are two indications to meet in the treatment of the disease first, to destroy the bacilli as far as possible by means of germicides, as has been advised in the paper read, and second, to diminish the reflex excitability of the ner-

> DR G C PAOLI advocated the use of ergot in pertussis In 15 cases it cut short the duration of

the disease

DR ROBISON, in closing the discussion, said was very anxious to hear from the senior members of the profession in regard to their belief in the pa-2 The fenestrated hthotrite should be employed thology of the whooping cough, because on that depends the treatment I know it was formerly be-3 Incision of urethra or bladder is safer than a heved to be almost of a purely nervous origin, or at least of reflex origin, and was treated internally by quinine, belladonna, ergot and opium, and antispas-Of late years it seems to me that it has almost been proven that the disease is of local origin, and it does not seem that we can fully deny the observations of Poulet and Berger that they have found the bacillus of pertussis I mention the treatment by germicides because all of these observers have noticed that the cough was lessened, the disease shortened and the patients obtained relief by local treatment, no internal medication being given that disease is a purely local one, due to bacilli, by the use of antiseptics we remove the cause of the disease and the accompanying nervous symptoms, and relieve the cough I desire to ascertain the general belief of the profession Is the disease a purely reflex nervous one, or is it due to the parasitic germs? It is generally considered a self limited disease Japanese call it the one hundred days disease, and probably in three months it will wear itself out, but it seems to me that by the use of these remedies we can shorten it, and are thus doing a benefit to our In regard to the insufflation of boracic patients acid in the nostrils, I think that is an argument eucalyptus, boracic acid, sulphur, illuminating gas in favor of this local treatment, for boracic acid is These had been applied by inhala a potent antiseptic. Sprays have been used for a tions, insufflations and sprays, but in many cases it long time, but the difficulty is in spraying the lar-

The use of powders has been in vogue for a is not preferable as an anæsthetic to ether long time, but there is a difficulty in carrying out decided renal irritation caused by the latter may pos a treatment of insufflation of powder by means of a sibly be a considerable factor in provoking uræma powder-blower, although when blown through the in such cases, where the second kidney is suddenly nostrils there is a fine dust formed which is inhaled taxed with an extra burden into the lungs Boracic acid acts precisely as carbolic acid that is inhaled

THE PRESIDENT, DR CHARLES T PARKES, reported

A CASE OF NEPHRECTOMY

(See p 9)
DR D T Nelson I was very much pleased at the doctor's instructions in regard to preparing the patient for these serious operations, and I believe we have considerable to learn in that direction as yet The method proposed I believe to be valuable in preventing shock If it is not wandering in a field that does not apply to the paper I would like to throw out another hint, which is that we prepare the alimentary canal previous to these operations, if you choose, make it antiseptic or aseptic by emptying it and subsequently giving antiseptic drugs, preferably naphthalin in 5-grain doses three times a day would like to ask Dr Parkes if, in making the inci- necessary, for the purpose of diminishing the size of sion, he was careful to preserve the capsule of the kidney and use that in facilitating his drainage? have had but one case of removal of a carcinoma I removed that from the anterior retous kidney gion, not knowing what I was going after I hoped it is very difficult to control the bleeding points I I had a cyst of the liver of a hydatid form, but on reaching it I found it was the kidney I opened the having the work under your fingers capsule of the kidney and preserved that, and after the kidney was enucleated, which was done much I cut down on the capsule, I am not positive whether more easily than I supposed it would be, I had no difficulty in closing the vessels in the manner the After ligating the pedicle it doctor has described was dropped into the bottom of the capsule and the walls of the capsule fastened to the wound, and dramage-tubes inserted so that there could be no communication with the peritoneal cavity proper The result of the operation was very satisfactory and there was a rapid recovery, although signs of the recurrence of the disease are appearing in other tissues

The fatal issue of this case DR W T BELFIELD through uræmia emphasizes again the necessity for ascertaining the integrity of the opposite kidney before removing the one under suspicion This precaution is especially needful in cases of renal tuberculosis, since the second kidney is so often the unexpected subject of this insidious disease In women the urine from the opposite kidney can be isolated by catheterizing its ureter either through the urethra or-if that fails-through a small incision through the vesico-vaginal septum whereby the orifices of the ureters are rendered accessible If the urine be thus obtained previous to the operation, and be found normal in quantity and quality, the surgeon can be reasonably confident that nephrectomy will involve no danger of uræmia at least, while, if this precaution be neglected, the greatest care and skill may be vitiated by uræmia through unsuspected disease of the remaining kidney

It is questionable whether for nephrectomy, or, indeed, all operations upon the kidney, chloroform dren, and has had three miscarriages, the last one

DR PARKES, in closing the discussion, said old incision recommended for exposure of the kid ney is an incision made parallel with the last rib, one nalf or three fourths of an inch away, a safe dis tance away, to enable the surgeon to avoid entering the pleural cavity With this incision the surgeon has always had a great deal of difficulty in exposing and uncovering the kidney and getting at the blood One operator relates that he proceeded all vessels right until he divided the upper half of the pedicle, You can see that then the patient bled to death the incision here recommended exposes everything If you will experiment on a dead body, to view with a healthy kidney—trying first the old incision and then this one, you will be convinced of the lat ter's worth I am convinced of another thing, that it is a good plan in all cases of pus degeneration of the kidney to open the cavities one after the other, if the tumor and also for the purpose of diminishing the congestion around the kidney The great amount of hemorrhage that occurs in this operation is from the enucleation of the kidney, and with a small incision think a great point is gained in every operation by

In reference to Dr Nelson's question as to whether I did or not I pursued the course which I follow in removing all tumors, to cut down on the tumor and to get as close to it and as far away from the I kept close to the dangerous points as possible surface of the kidney and away from the peritoneum

I do not know what would have been gained by This patient was secreting Dr Belfield's suggestion urine from the other kidney into the bladder, it was emptied out through the ureter and could be col lected and examined just as well as if the ureter had been catheterized In the first 24 hours the patient passed 7 ounces of urine from the bladder, in the next 24 hours 10 ounces, and so on up to the time of the occurrence of the unfortunate symptoms to The largest amount passed which I have referred was 17 3 ounces in 24 hours Up to that time there was nothing in the appearance of the patient that would make one think she was not going to recover All at once the change and the end came

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, October 6, 1887 THE PRESIDENT, JOS TABER JOHNSON, MD, IN THE CHAIR

DR Jos Taber Johnson presented a case of DERMOID CYST WEIGHING 50 LBS

Mrs P, white, æt 32, mother of nine living chil-

First noticed an enlargement about two years ago was taken for some portion of the child's body nancy I saw her at the request of her physician, Dr W P C Hazen, last June I was not certain of a diagnosis, and as the growth was not large, and her health being perfect, I advised delay I san her again in August She was still positive that she was pregnant, and as the weather was very hot and her health very good, I still advised delay I was cerabout pregnancy, of which I saw no symptoms constantly asserted that she felt exactly as she had when pregnant, and declared that she felt feetal tifully used to arrest it movements

I saw her again on September 7 The enlarge ment had been very rapid, she seemed to have doubled in size since I last saw her She gave up all idea of pregnancy at this time and was anxious for an operation I examined the uterus for the first time now with a sound, and found it empty and only 3 inches in depth September 20 was fixed for oper-On the 18th she went to Providence Hospi-Two weeks ago to day I opened the abdomen in the presence of Drs Hazen, M F Cuthbert, S S Adams, Fairfax of Alexandria and others tumor was unusually adherent over the anterior sur face, the adhesions seemed recent and broke down About three bucketsful of fluid were drawn off and the sac removed in the usual way Masses of hair blocked up the canula so as to cause the fluid to flow down the sac and around it Dr Cutts (H M) skilfully compressed the abdominal walls so as to prevent the entrance into the cavity

The patient made an uninterrupted recovery up to the third day, when she suddenly developed a temp of 102° It returned to normal the next day, but the next evening she had much indigestion and the temp was again 102° Her pulse but 96 This evening at 6 o'clock (October 5), temp 1010 pulse 84 I find, after repeated inquiry, that three days ago she ate quite heartily of lemon pie, and I think her prompt trouble is attributable to this indiscretion in diet, but I am somewhat anxious about her

DR Johnson also presented

OVARIES AND TUBES, CYSTIC AND ADHERENT

Miss M, æt 28, single Has been a sufferer at her menstrual periods since puberty, on three occa sions has had convulsions accompanying her painful menstruation Her life the last few years has been Has had little enjoyment, as any excess a burden in the way of excitement or fatigue increased her She was usually compelled to remain in bed a week and sometimes longer at every period Since the 10th of July last had been confined to her room with what appears to me to have been an attack of pelvic peritonitis She has been under treatment for had treated her constantly for the last two years

She begged for some operation which would reof the abdomen six months ago and thought she was move her pain. She jumped at the suggestion of pregnant, could distinctly feel a hard mass, which Battey's operation Indeed, she knew all about it As Dr Leach had explained to her the nature and efthis mass was movable, she felt more certain of preg-|fects of the removal of the uterine appendages, and she came to the hospital with the approval of her family, expressly to have them removed if the suggestion of her physician was approved

I examined her carefully and could find very little evidence of disease except great tenderness, and said I did not approve of the operation, but requested her to write out a brief history of her case tain of the presence of a cyst but was uncertain a result of my exploration she was confined to bed She for nearly a week So great was her pain that poultices, jodine, hot water and morphine had to be plen-After reading her letter and a consultation with Dr Leach, and a full explanation of the risks and effects to the patient, I agreed to make an exploratory incision, and if no trouble was found in the ovaries or tubes I should decline to remove them and would close the incision agreed to, and a week ago last Tuesday I opened the abdomen in the presence of Drs Leach, M F Cuthbert, Tyler, M Bruckheimer and others

I found the ovaries imbedded in a mass of adhesions, and cystic I thought they had been so much damaged by the manipulation necessary to their liberation that it appeared the wiser course to take them The gentlemen present all appeared to be of the same opinion I don't know that they are very much diseased, but I believe they were the cause of all her pain, and that she suffered from many attacks of cucumscribed peritonitis which caused the numerous adhesions found, and I don't know any other way to cure such cases I believe she will now be a healthy and happy woman, and if her menopause is produced that she will be free from her monthly recurring week of agony I know that she is delighted that they are out, and is entirely satisfied and fully understands what has been done and its effects She has had no rise of pulse or temp, has taken no medicine, and feels well enough to day to get up and walk

DR Johnson also reported a case of

COLPO HYSTERECTOMY FOR CANCER

Mrs R, white, æt 47, married, mother of five Had one miscarriage fourteen years ago, children since which time she has not been pregnant. She menstruated regularly and normally until sixteen months ago, when she missed her period and supposed the change of life had occurred Two months later began to have a profuse flow which has continued ever since without much intermission She could not feel certain which was hæmorrhage the time the flow was of a brownish color, watery and had a bad odor, shreds of tissue passed also The first examination was made by Dr Birdsall in Alexandria about three weeks ago, when, upon consultation with Drs Smith and Fairfax, it was decided a very long time She did not get better, and was to be epithelioma of the cervix extending up into the certainly growing worse She was brought to me at body of the uterus I was requested to see her by the Providence Hospital by Dr H E Leach, who these gentlemen, and did so two weeks ago to day I agreed with them as to the nature of the case, and

also that the sooner all the cancerous tissue was removed the better, even if it involved the extirpation of the entire uterus

The patient and her family were ready and anxious, and September 29 was fixed as the date for its per-I hoped to be able to stop short of the removal of the whole organ, and spent at least half an hour in efforts to that end We all felt that the total extirpation of the uterus offered the patient the best chance of recovering, as all the disease could not be gotten away without doing nearly as much violence as the removal of the uterus From the time the patient began to take ether, which was skilfully given by Dr H E Leach, until she was put back to bed, two hours had passed None of the cut tissues were sewed together, a rubber drainage-tube was put in and vagina tamponed with iodoform gauze The patient is now in her seventh day, with a pulse and temp of about 100° She has had no pain except in her bladder, which was probably irritated by the catheter during the Tampon and drainage tube were removed on the morning of the third day The discharge has been very slight and, with the exception of two or three days, free from odor She is now feeling well, takes much nourishment and appears to have a very fair prospect to get well, at least Whether the cancer will return from the operation time will show

DR KLEINSCHMIDT thought that the theory best accounting for the presence of dermoid cysts was the one ascribing their origin to misplaced parts or cells of the ectoderm in the process of folding in of the primitive layers composing the area germinativa These cells from the ectoderm retained their power of producing those structures which we know to be derived from the external integument, viz hair and A similar explanation could be offered for the production of other heterologous structures, e g, the formation of bone in nerve tissue, as illustrated by a case presented here by Dr Lamb, where bony plates were found in the medulla oblongata latter case portions of the osseous lamella of the mesoderm had, according to this theory, become misplaced among the cells of the ectoderm, which as we know, produces in the course of development the central nervous system as well as the external He thought this the theory accepted by most modern authorities in preference to the older explanation of "fœtus in fœtu"

Dr Kleinschmidt's explanation DR REYBURN In the male, teeth, is undoubtedly the correct one hair and even bone have been found in unusual places, which can only be accounted for by the obliteration or perversion of the developmental pro-He had a case about fifteen years ago girl was very much enlarged, and was willing to run the risks of an operation to protect her chastity Unfortunately she died The cyst contained bone, He reported the case and it gave hair and teeth rise to an animated discussion Many of the members thought it a mal pregnancy

DR SCHÆFFER of great interest

thology The first case he saw made an impression It contained jet black hair, over a foot in on him They are very rare Certain length, and teeth points in the theory mentioned by Dr Kleinschmidt seem to conflict It is not surprising to find these abnormalities in the male Monstrosities are found in all kingdoms He could recall an instance in which one fectus was partly buried in the abdomen of the other, as if it had turned a summerset normalities are not infrequently met with in twin pregnancies, one grows to maturity and the other remains undeveloped or takes on some unusual development Bone is not of the ectoderm or outer layer of the embryo, so how will Dr Kleinschmidt account for it in these tumors?

There is a decided difference of Dr King opinion between Drs Schæffer and Kleinschmidt. Dr Schæffer considers such growths degenerate in character, and Dr Kleinschmidt a part of the woman's fœtal development A part of the ectoderm remains and later in life develops into hair, etc. He has not studied the development of the generative organs very closely, so does not remember any fold that forms those organs Such growths are easily explainable on the theory mentioned by Dr Kleinschmidt

Can we find hair elsewhere? Dr Schæffer Then it must be due to misplaced cells Bone, teeth and hair remain after all else has been absorbed

The discussion of Battey's operation was postponed till the next meeting

(To be concluded)

SUFFOLK DISTRICT MEDICAL SOCIETY SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

Regular Meeting, November 9, 1887 DR V Y BOWDITCH, IN THE CHAIR DR F O Oris read a paper entitled, HINTS TO PHYSICIANS SENDING THEIR PATIENTS TO COLORADO

From a somewhat careful consideration given to the numerous health resorts throughout the world, and a personal acquaintance with some of them, I am prepared to say that I know of none possessing so nearly a perfect climate for many cases of phthisis, taking it all in all, as that of Colorado, or so nearly fulfilling the conditions necessary for the most suc-"Climatic treatment," cessful climatic treatment says Lindsay, "aims at removing the patient from a climate which induces an indoor and sedentary life to one where an outdoor life of healthful activity may be continuously enjoyed, without hindrance from Climatic treatment aims meteorological conditions at removing the patient from a comparatively sunless and depressing climate, which impairs vitality and lowers nutrition, to a sunny and tonic climate where appetite, digestion, and sanguification undergo such augmentation as may enable the patient to shake off The theory of such growths is or hold at bay the tendency to consumptive disease " These cysts are marvels in pa- All this, I believe does the Colorado climate

Having spent the last summer in Colorado, I was hours there long enough, perhaps, to appreciate the many bits of knowledge necessary and useful for the new comer, and not too long to forget or overlook them When the physician says "go to Colorado," he may not realize that the State is nearly as large as New England and the State of New York together, or must, therefore, give his patient more specific directions than these Generally, however, the physician means Colorado Springs, for there the larger number of invalids or "lungers," as they facetiously call them selves there, go, and undoubtedly this town is better prepared to care for the consumptives than most others in Colorado, for it is not an inconsiderable source of revenue to the inhabitants Scattering cases go to Cañon City, Denver, Salida, Boulder, and other places, but, with the exception of Denver, the accommodations are probably far better in Col orado Springs, if one is able to pay for them mostly young men, go out on a ranch, if they are strong enough to endure the hardships and privations consequent upon such a life, but they must be pre pared for poor food, and much of it is canned Wherever the patient goes, the physician under whose care he comes-and he should be under the observation of some medical man-should be informed by the home physician of the history and condition of the patient Better is it if the new physician is personally known by the one at home Moreover, the former will render great assistance to the recently arrived invalid by advising him as to health and have some dollars in his pocket at the end boarding places of good repute, and in wholesome localities, and, indeed, in a thousand other ways

the purest of drinking water from the melting snows of Pike's Peak are there perforce, on account of pulmonary trouble, are men of ability and skill There is no system of sewerage as yet, but one is in contemplation, and, I should say, was much needed The boarding houses are many and for the most part seem to offer good accommodations, the average price of board and lodging being from twelve to fifteen dollars a week What the physicians there advise, and which obvi ously is the best plan, is housekeeping, if the invalid is strong enough and is with friends, but rents are There is a good hotel, the "Antlers," where the new comer will spend his first few days until he of the society is much like that of a summer resort, invalid is essentially an out door one, which is very thirty five to forty-six cloudy days in the whole year, and from "October 1st to April 1st there is an averthe winter there is practically no rain, and one can

For some time after coming to this altitude (Colorado Springs being 6080 feet high), comparative rest and inactivity is enjoined, and probably with wisdom, but sometimes it seemed to me that this injunction was carried to an extreme, and that moderate exercise would have hastened the improvement or recovery Horseback riding is the exercise larger than England, Scotland, and Wales, and he par excellence at Colorado Springs, as elsewhere in the State, and horses are good and comparatively The rides are innumerable Out on the plains, to the various Canons, to Manitou, the Garden of the Gods, etc

> It seemed to me that there was no very great opportunity for one to find remunerative employment in Colorado Springs, for it is not commercially active Probably some of the other and more busy towns would serve better for this purpose My impression of Colorado in general, however, is that a man of sufficient strength, with energy and adaptability, who desires self supporting work, will not be long in find-As an illustration of this, I know a young clerk from this city who went to Colorado Springs for pulmonary trouble, but who was strong enough to be about and around after a little At the Springs he found a cattle-man who took him into his employ and sent him up into Estes Park to look after his He got the use of a good horse, and was paid a fair monthly salary, together with his board Possessing Yankee shrewdness he found an opportunity to preempt a quarter-section of grazing land at the same time, and now he bids fair to regain his

In summer Colorado Springs, judging from my experience, is likely to have many uncomfortably The majority of consumptives go to Colorado hot days, and it seems to be well for the invalid to Springs, a town of 7000, or more, inhabitants, with seek the coolness of the mountain somewhere and, moreover, it makes a pleasant and agreeable change The physicians, nearly all of whom after a winter spent in civilization, with its consequent and inevitable evils, to have something of the wild and free life of the mountains There are many of the so called mountain parks, near or more distant, and ranging in altitude from 7,000 to 10,000 feet high, which offer both a cool temperature and all the attractions of grand mountain scenery finds hotels in some, in others boarding ranches, and in more remote places he must go prepared to camp In all the food will be found more or less bad, depending upon the distance from any source of supplies, but unless very delicate, the invalid will soon learn to put up with it and will have such an has selected his permanent quarters The character appetite from the life and invigorating air that he can sit down and eat a piece of raw ham quite cosmopolitan, as one would naturally expect it and is strong enough for long trips on horseback, If one enjoys from the coming together of people from so many he can start on his horse from Colorado Springs, or different parts of the country The daily life of the Denver, and ride to the mountains and have his horse there for use For those who are delicate and need possible when one considers that there are only moderately comfortable quarters and care, there is Manitou Park, Idaho Springs, Salida, and Poncha Springs, near by age of less than one half a day of each week when village, most picturesquely located in a deep, narrow Georgetown, a typical mountain the patient will be deprived of sunshine " During gulch, on Clear Creek Cañon, and Estes Park, one of the most charming spots in all Colorado, and of sit on the veranda or be in the saddle every day, the which I shall speak a little more at length. It is one day of sunshine during this season being about eight of the smallest of the Colorado parks, and is about

ten miles square and 7,500 feet, about, above sea- the same invigorating influence in both places Lyons or Loveland, and from thence by a stage road in both places of twenty odd miles The journey is made in a day from Denver tlements in the park, the most of it being owned by the so-called English company Some years ago the Earl of Dunraven visited the place and was so much impressed with its beauty that he got possession of and three or four boarding ranches Ferguson's and it is best for them to remain in consequence of this James's are the best, at which room and board can The damper, but more quiet and soothing atmosbe obtained for about twelve dollars a week of these ranches consists of a number of small cabins of two or three rooms, some of logs and others of rough hoards, but one is very comfortable in them, and he is, or should be only in them to sleep food is fair for the mountains, about the same quality as in the Adirondacks It seems paradoxical that beef should be of poor quality, when all around are herds of cattle preparing for the Chicago market One has, however, every day, an abundance of the and from the latter city to Denver by the Chicago, most delicious brook trout

One of the great charms of the park is the nearness of the mountains On two sides are the great snowy ranges terminating in Long's peak, 14,272 feet high, the "Matterhorn of the Rockies" The air is of the purest, and almost every day is a sunny one Very rarely is it uncomfortably hot, and the nights Generally a fire is comfortable are always cool But once during a stay of six weeks there did I notice any dew, and one can sleep under the open sky without danger from dampness Many spend the in Colorado The cost of the journey there is from summer in tents, which dot the park over, but most of the cabins have chinks and cracks enough in them to let in sufficient air The flora is large and luxurious and the botanist will find continual surprises and delights in it Indeed I do not see how it is possible to find a clearer or more invigorating air, sunnier or bluer skies, grander or more beautiful scenery in the wise to make the ascent from the Missouri river to whole Rocky Mountains than here in Estes Park have known of a consumptive getting up from her bed in Colorado Springs to go to the park, and in a short time after her arrival there riding horseback The winter is not uncomfortable there, I am told, or very cold and so far as climate is concerned one could well live the entire year there if he could endure the loneliness Indeed it would be to me infinitely preferable to a winter among the snows and ice of the Adirondacks, and if a mountain health resort of such perfect climate existed anywhere in Europe, Davos would be deserted winter at Colorado Springs I would advise them to go to Estes Park about the middle of June, when occasional hot days come at the former place, and remain until the first of October If one rides horsebackand half the pleasure of the park is gone if he does seemed to endure the exertion and altitude about as not-it is the cheapest way to take your saddle with you and buy a pony there, which one can do for forty noticed by a physician in his own case When There is a mail once a day, dollars and upwards but no telegraph climate of Estes Park with that of the Adirondacks, trouble was kept in abeyance When, however, he I should say that it was rather warmer in the former descended to a lower level it recurred, or increased place, far dryer, and much more sunny One feels in severity

It is reached, from Denver, by railroad to night temperature is about the same, I should think,

In winter or spring either at Colorado Springs or There are but few buildings and set-elsewhere in the State, there are occasional high winds—"wind storms" they call them—accompanied with clouds of dust, which may produce an irritating and injurious effect upon those whose pulmonary trouble is accompanied with much secretion and who There is a small hotel there of moderate price, have sensitive throats. It may be a question whether phere of Southern California or the South may serve them better, which is again an illustration of the fact that no one climate suits every case of phthisis

> The best time to go to Colorado is probably in September or October—most delightful months there The best time to come East for a visit, I should think, would be either in May, June, or October The best way to go from Boston is, in my opinion, by the New York Central and Lake Shore Railroads to Chicago, Burlington and Quincy Railroad By this means there is but one change from Boston to Denver

> Clothing —One should have as thick winter clothing in Colorado as in this climate, for the mornings and nights are often very cold. In the sleeping room, moreover, one must make sure that the floor is tight and covered with a warm carpet. A fire should be made in the morning before the invalid

> Expense —It is expensive both going to and living seventy-five to one hundred dollars, and board in Colorado Springs, as I have said, is from twelve to fifteen dollars a week Rent of cottages is from fifty dollars upwards About the only thing that is cheap is horse hire

Effect from the Altitude—Some patients think it Denver gradually, so as to become accustomed to the altitude The majority, however, I think, go at once to the altitude at which they are to live, and generally, so far as I can learn, experience no especial discomfort or harm from doing so about ten weeks I lived at an altitude of from 6,500 to 7,500 feet or more, and climbed mountains, three of which were over 14,000 feet high, without experiencing the slightest discomfort Noi, indeed, was I in any wav unusually affected, except, perhaps, on three occasions Twice when on high mountains If one has passed the I had a slight headache, and the third time when at Leadville, which is over 10,000 feet high, nearly to timberline, it seemed to me that in walking I got out I have climbed of breath more quickly than usual high mountains with one of affected lungs, who A curious effect of the altitude was well as I about 10,000 feet high, at which altitude he generally Comparing my experience of the lived, the fever that accompanied his pulmonary

Length of Residence —In whatever climate one finds his lung trouble improving steadily, there he should remain, not only until all signs of mischief disappear, but, in many cases at least, as long as he I feel convinced that this is the safest and wisest plan, and I think that physicians of experience are gradually growing to this opinion This is especi ally true of the Colorado climate, which is such a radical change from the one the patient is likely to I believe the slow improvement, or lack of any improvement, in many cases is due, partly at least, to the worry over the enforced exile. and eager watching for the time when they think they will be able to return to their homes often noticeable how quickly and permanently those improve and recover who take up their residence in Colorado, and settle down to permanent llving there, with their friends and family about them trary is also observed with those who make it a mere health resort, and are separated from their As, for instance, a wife from her family and friends husband, or a daughter from the rest of her family

DR F I KNIGHT There is a point that ought properly to come up, although Dr Otis did not notice it in his paper I think a warning ought to be given, whenever the subject comes up for consideration, at any rate when it is presented to those who are not familiar with the subject, in regard to the cases which are to be excluded from that climate It is too much the fashion, when a climate becomes popular for the relief of any disease, for all patients with that disease to be hustled off there is just as much a mistake as it is for every case of pneumonia to be treated with the same drug It is very much like the treatment of disease with a little book of symptoms

There are certain kinds of consumption that will die very much quicker in Colorado than they would if they stayed at home, and it is certainly very much wiser for a physician, unless he has considered his case for a long time, and perhaps has counsel upon it, to keep at home cases of very advanced disease, also, to keep out of that climate cases attended with a good deal of fever, and very possibly, also, those cases of a highly wrought nervous temperament To be sure some of those latter cases do well in Colorado, and some even of the advances cases

One case I have in mind, which was taken out there without my consent, and not exactly against my remonstrance, which after a long time did do well, although it was a case of very advanced As a rule, it is very much safer not to be in haste, at any rate, to send these cases to a high It certainly has been my experience, and I have had cases of pulmonary disease treated in almost every climate in the world, that the cases of lung disease that are free from fever, and where there is tolerable strength and constitution to start on, do far better in a climate of that kind, a high mountain climate, than in any other, and I think that all

activity of the disease has been mitigated at home, that patients may be removed there with safety, and this is a thing for consideration

There is another point which we must also bear in mind, which must be urged upon the minds of men, that in regard to it they may not act hastily, and that is in sending poor patients off there with the idea that the climate is going to do everything for As a rule, if a man has extensive disease of the lungs, and is going to work for a living, he had better be advised to save his money and stay at He had better do as well as he can among his friends, and not waste the little that he has accumulated in a change of climate, for his money will go in a very short time out there, and he will be left stranded and unable to work It is a great pity, it seems to me, to send off, as some physicians seem to be in the habit of doing, every case of pulmonary disease, without regard to their circumstances Almost every day cases come to me who have been urged to go to Colorado or California, or New Mexico, patients who have perhaps accumulated a few hundred dollars, which is all they have in the world, and they are advised to make a change of climate on account of lung disease They would be left stranded I should say that unless the patient had very little disease, and it was perfectly clear that he was able to work, and certainly it is not so with the most of these cases, they would better be advised to stay at home, unless they have means of living a considerable time without any active work

DR ALBERT N BLODGETT I had an opportunity, some years ago, of investigating the climate of Colorado, although not so extensively as Dr Otis has done, and I was struck by one or two things that have been mentioned, and some that have not been alluded to In the first place, the distance is so great, that many patients who start in fairly good condition are very greatly fatigued by the journey Under any circumstances it is extremely taxing for an invalid The journey is a long one, and I think that, with ordinary expedition, a week would be thus consumed I have seen patients who, from fatigue, have seemed to die sooner there than they would have done if they had remained at home I have supposed that cases in an acute stage of pulmonary phthisis should not be sent to that climate I think the abruptness with which the change should be made, and the high altitude reached, for persons whose pulmonary structures have been invaded by phthisical disease, is a question that should have more consideration than is usually given it seen healthy persons suffer from shortness of breath on arriving in Colorado to such a degree as to make any sort of exercise burdensome for some days have seen others, in Switzerland, who have had a "rush of blood to the head," in an altitude as high as Colorado Springs, which was relieved by frequent nose bleeds I have seen the same thing in Col-Perhaps it would be better to break the climatologists are fast coming to that opinion In journey for the sake of lessening the fatigue, and the cases of very advanced disease, in those cases also in the hope of accustoming the pulmonary particularly where there is a good deal of febrile dis- structures which are already diseased, to the rarer turbance, it is possible that after a time, after the air, rather than to make a hasty journey, and perhaps put a feeble patient in a less favorable condition for improvement than he would be in with a little more attention to this precaution I can certainly verify everything that has been said, so far as my experience will go, in regard to the wonderful climate which is found in this part of our country I had an opportunity of seeing a part of Colorado, although it was a very small part, located in the vicinity of Denver and Colorado Springs, and the parts between, and I never saw anything like the noticeable clearness of the air in this region The exhilaration is something remarkable—certainly in a healthy person—and I have no doubt it would be the same, to a certain degree, in a sick person

I cannot help thinking that the climate of Colorado is the nearest to a typical climate for consumptives which we know anything about, but I believe that far greater care is requisite in the selection | It seems to me that it is a mistake to send other than of cases, and far more caution in changing to that select cases climate than has heretofore been observed

Two years ago I made a pretty careful study of the Appalachian range in Georgia I believe there are certain of the Alleghany ranges which ought to be taken into consideration in sending patients from our own vicinity There is the change in life, the distance in reference to diminished expense, and the expense of living after one is there In the western sections there are a great many places where one may live profitably by making it a home for investment So far as elevation is concerned, there are valleys in certain sections up to 2,000 or 3,000 feet This is inconsiderable in comparison with Colorado, but very considerable in comparison with other ele-Eight-tenths is still primeval forest, which vations equalizes temperature

It is not as dry a climate as Colorado The rain fall is probably not less than in New England, though it is placed on the maps as being dryer than any other section—than the Colorado ranges I saw a number of invalids who felt sure that they could not live on our sea coast border, men who had cavities and had had hæmorrhages, and who were in pretty I have, myself, sent forty or fifty patients to this section, and, although they have different results, in the main it is as satisfactory as double that number of cases who have gone to Colorado Ample board can be obtained with half the money The expense of going is less than half, and sometimes a distinct advantage is gained in the fact of the invalid being much nearer home The air there is as pure as can be found in any part of the world The mountain tops are covered with snow three or four months, the valleys only three or four days at a time The locomotion is on horseback par excellence Every other way is uncomfortable in the extreme

There are one or two DR R W GREENLEAF medical questions relating to it in which I differ from what Dr Otis has said First, in regard to whether the patients who are sent there ought to go right about their exercise or not It seems to me that it is to purify the air of a room occupied by phthisical would be far wiser for them to remain at rest for A well person is quite fatigued by the some days altitude, even in such a place as Colorado Springs I was perfectly well all the time I was there, but communication, by the aid of a tube, with a chimney

even a half-mile fatigued me for some days, after that I could walk indefinitely as at home Instead of remaining in Colorado Springs or in the towns. where there are all the drawbacks of dust and rest dence in cities, why is it not wiser to advise the patients, if they can afford it, to go into the mountain regions and be in camp all the time? To be sure, some things are hard, but they can be lightened in many ways Changes of heat and cold are very It was very warm at midday, and the water was almost frozen at night It seems to me that it is far wiser for the patient to go into the mountains as soon as they are strong enough to undergo such extremes, so that they could be out of doors all the time I was very glad to hear what was said about the selection of cases, for I met many cases who were coming back simply to die

DR OTIS I did say that comparative rest is en joined, and probably is essential I did not mean to say that I believe in activity as soon as the patient arrives in Colorado Springs It seemed to me that some of the patients, after they had been there a year, were sitting about on the veranda when it did seem as if they would do better if they moved In regard to the patient going at once into the mountains, the practical difficulty is that you cannot get good food Unless he is pretty well and strong, the patient could not endure it I don't quite agree with what Dr Knight said about poor people going It seems to me it makes a difference what sort of a person it is I remember one poor young man with no money, a clerk in a store employer gave him a present of fifty dollars, and he went out there He had serious trouble with his lungs, and was told to keep still He got a horse and rode about, and soon made friends with a cattleman who employed him and paid him a fair monthly salary, and he seems getting on well I remember another instance of a young man who had money enough to stay awhile, and found employment He finally bought his employer out I think it depends on the kind of man that goes

Apparatus for Purifying the Air of Rooms of Phthisical Patients - Nervous Predisposition in the Ethology of Facial Paralysis—Therapy of Chronic Metritis—A New Truss

At one of the last meetings of the Academy of Sciences, Dr Brown Séquard presented an apparatus invented by M d'Arsonval, the object of which This apparatus is bell-shaped and placed patients at the head of the bed, under which the patient It is so arranged as to be in constant breathes

which is heated by gas, a candle, or a lamp The chimney, which also communicates by a tube with the external air, draws to it all the air that escapes from the lungs of the patient and is expelled outside so that it does not mix up with the atmosphere of This subject was discussed at the last the room meeting of the Société de Biologie, when some of the members present did not see any great advantage that the apparatus described above had over keeping the windows constantly open for the renewal of ally to which it belongs by its origin Moreover, Dr Strauss, while admitting the inconveniences that may result from breathing con patients does not contain microbes Tyndall has shown that this air was optically pure, it contained the presence of a single bacillus in the air expired by rise to the lesion is cured his phthisical patients same results that, as regards microbes exclusively there is no in- it depends convenience whatever to breathe the air expired by phthisical patients

This certainly does not accord with the experience of the majority of physicians, and Dr Brown Séquard, in responding to the above remarks, observed that it is well known that phthisis commits greater ravages in the cities than in the country, and, generally speaking, in all places where the population is not on it, as is generally done dense and conglomerated In prisons the mortality from phthisis is considerable. It has been remarked also that soldiers affected with tuberculosis enjoy better health when they are out in the camp than when they are confined to their barracks All these considerations, the speaker added, demonstrated the dangers of breathing confined air, and that allowing abstraction for microbes, as this air certainly con tains other principles injurious to the health

In an interesting article on the part played by nervous predisposition in the etiology of facial paralysis, published in the Archives de Neurologie, Dr E Neumann observes that, when an individual is affected with facial paralysis, the hemiplegia cannot be referred to an organic lesion, one is disposed to accuse the cold, and to impute the malady to its depressing influence on the body, and hence the reason why the affix "à frigore" is sometimes applied to it Such, however, is not the opinion of the author, and, founding his observations on numerous clinical facts, Dr Neumann thinks that neither the cooling of the themselves to determine, in any person not pre disposed, paralysis of the face These circumstances are only accessory factors which rôle of provoking agents the a soil prepared in advance predisposition

cedents of the patient, which will disclose an hereditary nervous condition without which all the determinant causes would be absolutely powerless to provoke a hemiplegia of the face In conclusion, Dr Neumann suggests that rheumatic facial paralysis should be definitively removed from the category of maladies included under the term "à frigore," to be enrolled among the other maladies of the nervous system, and to take its place in the great neuro pathological fam-

In his lectures on the Therapeutics of Chronic Metritis at the Lourcine Hospital, Dr Martineau fined air, observes that the expired air of phthisical endeavored to show that the treatment of metritis is not single, as it was said to be by the older gynecologists, that this disease did not rest on one lesion neither microbes nor solid particles Prof Grancher only, and that it did not suffice to cure this lesion to declared that he had never been able to discover | declare that the uterine inflammation which gives The curability of metri-M Charin arrived at the tis is possible only on the condition of treating the Consequently, the conclusion was general malady, constitutional or diathetic, on which The author has thus removed the treatment of metritis from the narrow limits of anatomical and symptomatic localization

At a recent meeting of the Societé de Chirurgie Dr Lucas Championnière exhibited a new truss of his invention for patients who have been operated It consists of a simple elastic band on for hernia with a pad, which is placed above the cicatrix and

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Pathology and Treatment of Diphtheria—Sarcoma

At the last meeting of the County Medical Association Dr J Lewis Smith read a paper on Present Opintons Regarding the Pathology and Treatment of He said that while the investigations Diphtheria concerning the etiology of the disease had clearly established its microbic origin, the microbe which was its specific principle had not been positively demonstrated, and he then went on to speak at some length of the bacillus observed by Loeffler and described by Klebs in 1883, cultures of which to the twenty-fifth generation, inoculated in guinea-pigs and body nor the nervous derangement can suffice of birds, produced a whitish exudation at the point of inoculation The investigations into the microbic origin of diphtheria lend considerable support to play the theory that it is primarily a local disease, and efficacy that in certain mild cases it never becomes conof which would doubtless be nil if they did not find stitutional, or is constitutional only in a very The preponderating feeble degree Nevertheless, those who believed part in the etiology of paralysis of the seventh pair that diphtheria was primarily constitutional based of nerves must be ascribed to hereditary nervous their opinions on facts which presented strong evi-When a physician finds himself in dence in favor of their view, such as the inoculation the presence of a subject affected with facial paralysis period of six or seven days in certain cases, the early manifesting itself independently of any appreciable occurrence of nephritis (even within 24 hours in maorganic lesion, he should make an inquiry into the lignant cases), and the existence of very severe and family antecedents as well as into the personal anteof the mucous surface had been so trivial as to be instances were also mentioned showing that the area scarcely appreciable The mooted question as to whether diphtheria is primarily constitutional with small, and therefore unlike that of pertussis and local manifestations, or whether its nature in this respect varies in different instances, he thought, therefore, must be considered as still undetermined

As to the propagation of diphtheria, the statistics of Dr C W Earle, of Chicago, showed that the disease was as severe and fatal in salubrious localities in the newly settled and mountainous States and Territories of the Northwest, when it happened to be introduced, as in the foul air of large cities. though dampness and decomposing animal and vegetable substances in rural localities, as in cities, increased the prevalence of the disease His statistics also showed that diphtheria may be communicated fully studied the infectious diseases in children's inlong distances by railways, and probably by merchandise, and they demonstrated its extreme contagiousness from person to person In the cities there was abundant and melancholy proof of the causative | that one principal reason why there is such a differrelation of foul air, whether arising from sewers or from stagnant filth, to the disease, and Dr Sternberg. in his recent Lomb prize essay, had expressed the in different localities and at different times. Accordopinion (which seemed to be borne out by observations relating to the etiology of diphthena), that the diphtheritic germ, once deposited in damp and foul places, is probably propagated independently of the sick Thus, in New York city prior to 1850, although foul sewers and unsanitary conditions existed, there was no diphtheria, but in the decade following 1850 diphtheria was introduced, and its germ made its way into the sewers, where in the filth underground it found a nidus for its propagation, so that now, whenever sewer gas escapes into the domiciles of the city, it is laden with the germs of this disease

The amazing vitality and power of propagation of the diphtheritic germ are apparent when we reflect that it has permanently infected the filthy-flowing years, ½ grain current of the sewers in every part of a great city, sewers which in their ramifications extend for hun-|ment by turpentine, both internally and in sprays dreds of miles It is propagated chiefly by exposure of children to the sewer gas, carrying with it the diphtheritic germ, which exudes from this widely extending underground culture-bed, and to walking cases of | teaspoonful, given from one to three times a day in diphtheria, often so mild that there is little or no complaint of the throat or impairment of the general it as a spray, and of 36 cases treated in this way, In Dr Smith's opinion, the germ of diphtheria is of such a nature, and quickly becomes so established in a sewered city, that it can never be in teaspoonful doses, reduced the temperature in 47 "stamped out," as cholera and yellow fever may be, by the active measures of health boards or by legislative enactments, although these may doubtless do much in the way of protection He also alluded incidentally to the possible communication of diphtheria to man from animals, and stated that recent acid, potassium chlorate, etc., 32 5 per cent died investigations went to show that it may be thus communicated from poultry, and especially from pigeons

In speaking of the area of contagiousness in diphtheria, Dr Smith said that Dr Lancey had cited cases to show that this area is limited to a few feet, and that Dumez had stated that in a school in which the boys and girls in the same hall were separated by an open space a few yards wide, diphtheria prevailed stating that he had seen it cause symptoms resemamong the girls, but did not attack the boys Other bling those in extreme cedema of the lungs In

of contagiousness, like that of scarlet fever, was measles, which, when they entered a domicile or asylum, usually attacked all the unprotected chil-Dr A V Meigs, of Philadelphia, in a paper dren published last year on the propagation of the com mon infectious diseases of childhood, placed diphtheria with scarlatina and typhoid fever in one group Diseases of this group, he said, seemed to be more subject to endemic or local influences than were measles and pertussis, not spreading over wide com munities like the latter, and hence, by strict quarantine and preventive measures, their wide extension was more easily prevented Those who had carestitutions and elsewhere, Dr Smith thought, would recognize the truthfulness of this distinction

In taking up the subject of treatment he remarked ence of opinion in regard to the value or remedies was because the disease varies so greatly in severity ing to some observations made by Lunin at the Oldenburg Hospital in 1882, turpentine was found to be the most useful agent in the fibrinous form of the disease, and tincture of chloride of iron in the phlegmonous and septic forms By many physicians bichloride of mercury was at the present time considered the most efficient remedy, but it was necessary to use it with great caution, especially in the form of a spray, or where it was given internally at the same time that the spray was employed Dr Smith thought that the quantity of bichloride that could be safely administered to children of various ages was about as follows To a child of 2 years,

1/6 grain, 4 years, 1/4 grain, 6 years, 1/3 grain, 10 He devoted considerable attention to the treat

and fumigations, and quoted a number of favorable opinions concerning its use |Thus Schenker employed it internally in doses of from 10 minims to 1 milk, sugar-water or gruel At the same time he used with the use of alcoholic stimulus as required, in addition, 31 recovered Sigel stated that turpentine,

cases, in 14 of which the necessity of tracheotomy was apparently obviated by this remedy whole number of cases treated by him with turpentine, 87, death occurred in 149 per cent, while in those treated with bichloride of mercury, salicylic

Among the other agents considered by Dr Smith were sodium benzoate, bromine, calomel, quinine, copaiba, cubebs, pilocarpin, tincture of chloride of He spoke in strong iron and potassium chlorate condemnation of the use of pilocarpin (which has been highly lauded by some authorities), on account of the disastrous results liable to be produced by it,

speaking of chlorate of potassium he gave the following prescription, which he said had been long and favorably known in New York, and was probably more frequently written, with some variations in its proportions, than any other in diphtheria

Tinct ferri chlor Potass chlorat git x Acid muriat dilut Syr simplicis

Dose, I tablespoonful every one or two hours

The tendency, however, had been in late years to diminish the amount of potassium chlorate, or even to omit it altogether, from its known irritating action on the kidneys, which are so prone to inflammation in this disease, and he thought it should no doubt unne

In conclusion, Dr Smith spoke of the solvent action of papayotin and trypsin on diphtheritic mem-Dr A Jacobi had met with good results from the latter, employing a mixture of r part of papayotin and 2 parts each of glycerin and water solvent action of trypsin, like that of lime water, was increased by using it in connection with an alkali, and he suggested the following formula for a spray

Sodii benzoat 51-11 511-111 Sodii bicarb Trypsin Ol eucalypti Liq calcis.

At the conclusion of Dr Smith's paper, Dr A Leale said that in order to overcome the difficulty of feeding the patient so commonly met with after intubation or tracheotomy, he had been in the habit of resorting to a very simple but efficient device, which he thought ought to be more generally This was the introduction of a No 8 velvet-eyed rubber catheter into the stomach by way of the nose, and the injection through it, by means of an ordinary syringe, of any kind of liquid food that was required

On the same evening Dr Frederic S Dennis read a paper on Selected Cases of Sarcoma in Bone, which was illustrated by a large number of interesting specimens and microscopic sections In concluding if he called special attention to the importance of the

following points

1 An early diagnosis 2 Complete removal of the disease by amputation of the part in which it is situated, and not by enucleation of the tumor The careful watching and recording of the subse quent history of the case 4 The recording of all cases of sarcoma in bone coming under observation, together with the microscapic appearances of the growth 5 In collecting statistics of this disease the discarding of all cases in which the microscopical appearances are not fully recorded

THE SUDDEN DEATH OF DR J Reply to Dr H C Markham

ports the melancholy death of a young and accomplished physician, Dr J E Chandler, of Rowley, Iowa, his death having taken place suddenly and almost immediately after the extraction of a tooth "Some years ago the deceased Dr Markham says suffered a severe rheumatic attack although not arthritic in type (italics mine) For two or three years he has developed heart symptoms, including a mitral systolic murmur" In The Journal of Dec 3 Dr Markham, in his reply to Dr Babcock, makes further comment upon this unfortunate death, and it is my honest conviction that, when he says death was due to "a fatal faint, and not heart disease," he draws a conclusion not warrantable in this case, when all the known facts are taken into consideration always be omitted if any albumin appeared in the therefore beg to differ with Dr Markham in this instance, with all due courtesy, and with a due regard for his unquestionable professional ability

Take, if you please, an hypothetical case with a "mitral systolic murmur" indicating but a slight orgame lesion of the heart, and in addition to this a certain degree of general debility, and I admit the possibility of death taking place by ventricular overdistension, and during no greater mental excitement and physical exertion than Dr Chandler probably expended in extracting the lady's tooth ther, I am not prepared to deny, in a rare and isolated case, the bare possibility of death occurring under similar mental and physical circumstances where ante mortem and post-mortem examinations fail to suggest the organic heart lesion Chandler's case, however, I propose to demonstrate the probability, if not the almost certainty, of his "fatal faint" being due to grave and long continued cardiac disease, the direct sequela or accompaniment of acute inflammatory rheumatism of a severe and In other words, the probability protracted type that compensation had been ruptured and grave dilatation established," suggesting that the immediate cause of death was from paralysis from ventricular over-distension, the result of the heart's muscular mability to perform the extra amount of labor instantly demanded to continue the existence of the

patient

At the late meeting of the Buchanan Co Medical Society, Nov 17, 1887, at the request of the Society Dr S G Wilson, in the presence of Dr Markham, gave his remembrance of Dr Chandler's case, and referred in particular to the severity of the acute in flammatory rheumatism from which Dr C suffered One attack, during his attendance as a student in the Medical Department of the University of Iowa, occasioning his return to Independence, Iowa, at which place the writer of this letter, during a social call and in the presence of Drs Wilson and Powers, saw the swollen joints of Dr C Dr Wilson re members the positive establishment of heart-trouble, and is quite sure the murmur developed was considered at the time mitral Not only this, but he remembers having made the diagnosis of endo or pen-He made frequent examinations of the heart after the acute symptoms had subsided, and Dear Sir —In The Journal of Nov 12, 1887, found the endocardial murmur persistent and easily Dr H C Markham, of Independence, Iowa, re- recognized, his last examination of this character

having been made two or three years ago Now we all know too well the great likelihood of cardiac disease occurring in cases of this character also know that in the majority of cases the diseased condition originates in the left side of the heart in that portion of the endocardial membrane entering into the structure of the mitral valve, and that, again, the majority of mitral lesions revert back to inflam matory rheumatism Suppose Dr Wilson had entirely failed to remember his location of the endocardial murmur when last examined two or three years ago, and we have remaining his positive assertion of recognized cardiac disease at that date, and this, taken into consideration with the fact that in a large majority of cases it would, under similar circumstances, be mitral, establishes a very probable diagnosis, the prior presence of inflammatory rheumatism being beyond question This was two or three years ago, and in the absence of further examinations, we are justified in suggesting the possi ble implication of other regions of heart, perhaps of the aortic valves And to increase the probability, permit the suggestion that Dr Wilson's superior qualifications, characteristic caution, and thoroughness, render his statements peculiarly reliable. I look upon it as an illogical deduction to consider Dr Chandler's one of those rare and phenomenal cases above referred to, in the face of unimpeachable tes timony showing that he suffered from acute inflammatory rheumatism, followed or accompanied by endo- or pericarditis, and the establishment, from this cause, of valvular lesion, the natural and ordinary result of which is hypertrophy and dilatation, in which latter condition his "fatal faint," although not a frequent occurrence, is readily accounted for Dr Markham treated him for debility, functional impairment of the liver, nausea, and loss of appetite

As Dr Babcock says, "It is not uncommon for pa tients with heart disease to refer their symptoms to some other organ than the one affected more, the Doctor was an energetic man, very likely more, the Doctor was an energetic man, very likely A G O, December 23, 1887 to perform his daily duties without complaint, hence First Lieut Wm B Banister, Asst Surgeon, ordered to proit is reasonable to assume that his condition was far graver than he himself would admit or others recognize" Dr Markham failed to have his suspicions aroused and examine the heart Yes, the writer of this letter has in his mind a remarkably distinct remembrance of a case located by himself as an attack of malignant malaria, the patient having a "close call," but making a brilliant recovery There is but little doubt but that it was a case of "femoral her-At a time when malaria was in almost every household, overworked, hurried, and in the absence of certain prominent symptoms, I made this blunder I failed to examine the important region that it was good for me to have been there" When by an innocent oversight we occasionally make an important omission or commission, if properly assimilated it will nourish more careful investigation and increase our usefulness in our profession Never before have I even attempted to burden medical P A Surgeon A D Bevan, resignation accepted, to take effect I do so now purely in the interest of Respectfully. correct conclusions

A CLINICAL LECTURE

STRICTURE OF THE URETHRA

Delivered at the West Side Free Dispersary, Chicago, Ill BY HENRY J REYNOLDS, M D,

PROFFSSOR OF DERMATOLOGY IN THE COLLEGE OF FINSICIANS AND SUR GEONS, CHICAGO ILLINOIS PROFESSOR OF SKIN AND GENITO URINARY DISEASES CHICAGO FOLICLINIC CHIFF DERMA TOLOGIST TO THE WEST SIDE FREE DISTPNSARY
SURGEON TO THE DEJARTMENT FOR GENITO
URINARY DISEASES WEST SIDE FREE
DISPENSARY CHICAGO (Reported by WILLIAM WHITFORD)

GENTLEMEN There are two classes of cases where we are always very liable to meet with stricture of the urethra First, those cases that come to us with a history of having had a continuous gleet for sever al months or years, preceded by one or more at tacks of gonorrhœa Second, those cases that ap ply to us for relief from an attack of retention of As the case we are about to consider to day comes under the first class, we will now confine our remarks chiefly to stricture as met with in this class of cases

It is almost a natural consequence, after repeated and long continued attacks of urethral inflammation, that some contraction of the urethral passage should be the result, and organic contraction once fully es tablished, for mechanical and other reasons, natur ally tends to perpetuate the inflammation wise, therefore, when consulted for this class of cases, to always investigate the condition of the urethra as regards stricture, etc

Case — The history of this case is as follows tient is 39 years of age, and since his third attack of gonorrhœa, fifteen years ago, he has had almost a continuous discharge from the meatus, which has several times assumed an acute character He is obliged to pass his urine a little oftener during the day than is natural, and to get up from one to three times during the night for this purpose three months ago, he says, he was cut for stricture at some point near the meatus, but the symptoms have not been in any way relieved by the operation

Now, in order to know whether this man has stricto what his normal urethra should be Though not universally conceded, it is a pretty generally acentire organ A penis measuring four inches in cir-

stricture exists, and the meatus be sufficiently enlarged, to admit a No 40 French sound, which is about 24 English One three and one half inches in circumference will admit a No 35 French, which is about 22 English, A circumference of three inches would indicate a calibre of 30 French, or 18 English, Though an ordinary inflammation or congestion of the urethra may naturally somewhat diminish this calibre, I think it fair to presume that, when we find at certain points a deviation of several sizes from this rule, some stricture exists surgeons might claim, however, that a slight amount of contraction as indicated in this manner, would not be sufficient to demand surgical interference, but I know no reason why, if we pretend to treat or cure stricture at all, the original calibre should not be completely restored

Examination —We find in this case a circumference of three and one half inches, and would therefore expect a urethral calibre of about 35 French, or 22 English Now, the use of an ordinary sound of

uniform diameter through its entire length would be sufficient to determine the presence of stricture, but as it would be impossible to definitely locate one or more strictures in this manner, we make use of what are called "bulbous sounds," such as I now show

Passing the largest size that will be admitted, or beginning first with one about the normal size and constantly changing to smaller size till we find one that will pass through the stricture, then as it slips through the strictured point the bulb detects the extent and location of the contraction, and so on with the deeper strictures, which, if any exist, are generally found to be smaller than those nearer the meatus The meatus is usually the smallest part of the urethral passage, but in this case it was cut at the time he says he was operated upon for stricture, and is now nearly as large as we have indicated the urethra should be We find, as you see, a point extending from two inches to three inches from the meatus which will only admit a No 21 French bulb, which is about 12 English Farther down, at five inches, we find a point which will only admit a No 19 French bulb Now, while we find a ureture or not, let us first get some approximate idea as thra here with a calibre abundantly sufficient for the free passage of urine, it is nevertheless diminished in its calibre nearly one half at two different cepted theory, that the size of the urethra should points, and while a chronic gleet may at times be always bear a given relation to the size of the met with wherein there is no stricture, it is entirely probable in this case that the discharge is, if not cumference will almost invariably be found, if no actually caused by this contraction, certainly aggra-

vated or prolonged by it, and as we find here a mechanical imperfection of the urethra, the rational procedure in treating the case, or endeavoring to cure this gleet, would be first to make the urethral canal a mechanically perfect one We will, therefore, for the time being in treating this case of gleet devote our entire attention to the removal or cure of these strictures

Treatment — There are four principal methods for treating stricture of the urethra First, gradual dila-Second, rapid dilatation or divulsion electrolysis, or the use of the urethral electrode Fourth, cutting or urethrotomy As there are undoubtedly cases in which for numerous reasons each of these methods may be used to advantage, I may, while the patient is being anæsthetized, briefly describe them

Gradual Dilatation -To enlarge a stricture by the process of gradual dilatation, conical steel sounds, similar to the ones I now show you, are generally used The largest sound that will pass through the strictures into the bladder without particular force, or causing the patient any severe discomfort, is to be passed and the same process repeated about every third day, now and then resorting to a larger instrument, as the condition of the canal will seem to permit In this way, very many organic strictures of the urethra may, in the course of several months, be enlarged to nearly, if not quite, the Some of the objections, however, normal calibre to this method are its slow process, the repeated lia bility of its provoking reflex urethral troubles, such as the so called urethral fever, prostatitis, cystitis, etc, especially if the urethra be very irritable, and the fact that in order to maintain the calibre acquired, the occasional passage of the largest sound, which has been used, seems generally to be necessary afterwards

Rapia Dilatation —By rapid dilatation or divulsion, we mean the restoring of the complete size of the urethra at one operation by the use of an instrument, such as I now show you, known as a "urethral di vulsor," an instrument which, as you see, when passed into the urethra, may be expanded by various devices, and made to rupture the contracted tissues In strictures of the deep urethra the tissues, owing to their more unyielding character, may be generally ruptured by this process, and the effect or result is then very similar to what it would be if they had But in strictures anterior to the scrotum the tissues, instead of always rupturing during the process of divulsion, frequently stretch like India rubber, as it were, and immediately come back in this case, and I think the best in all bad cases, when the tension of the instrument is removed, leaving still some contraction, and the latter is one of the principal objections to treating strictures by this known as the "Otis divulsing urethrotome," which method

Electrolysis -Though there are to me some very important objections to electrolysis as a scientific to use it in this case method of treating stricture of the urethra, it never- large enough to admit a No 22 English, which is the theless has its merits, and is in suitable cases, to say size we propose to pass on this man, after the stricthe least, a very useful adjunct in the treatment of tures are removed we enlarge it slightly by putting by even its most ardent advocates, that strictures drawing the blade, cutting down towards the frænum,

cannot well be enlarged to more than about a No 14 or 16 English in size, by this method, it is therefore best, if not only adapted to the treatment of stric tures of small calibre In treating strictures by this method a galvanic battery, so constructed as to give the best electrolytic effect, is required A urethral electrode, such as I now show you, which is a metallic sound insulated to within about one-half inch or so of its tip, and so arranged that it can be connected with the negative pole of the battery, and which should be several sizes larger than the stricture to be treated, is passed down and pressed against the stricture The circuit is now completed by placing the positive electrode on some adjacent As to the strength of current required, no definite rule can be laid down, with the ordinary McIntosh battery, from eight to sixteen cells will be necessary The electrode is now carefully and continuously pressed for several minutes until it finally passes through the stricture, causing, during the continuance of the operation a certain amount of stinging, burning pain This operation is to be repeated every week or ten days, using at each time an instru ment several sizes larger than at each preceding This, then, would complete a rather imperfect description of the method of treating strictures by electrolysis

As to the merits of this method, it is an unquestionable fact that a larger instrument, if it contains an electrolytic current, can be passed through a very small passage than could be done without the current, as it seems to dissolve its way in, as it were This I frequently see demonstrated in a very striking manner during the removal of superfluous hairs by electrolysis, when the needle, if the current be on, will pass into the tissues without any perceptible resistance Owing, however, to the fact that with the use of a very large electrode the current becomes greatly diffused, very little electrolytic action takes place, and the effect then becomes very similar, if not the same as from the use of an ordi-It is obvious, therefore, that this, as a nary sound method for restoring the complete calibre of the urethra, is an imperfect one I occasionally use it, however, when I have a stricture so small that I cannot get any other instrument in, as it is, I think, the best method for enlarging a very fine stricture, preparatory or preliminary to the more radical method of divulsion and cutting, which I always prefer ultimately to resort to, and which I shall now describe

Cutting Operation -We now come to consider a method that is the most radical, the one we shall use namely, internal urethrotomy I think the best instrument ever devised for this purpose is what is may, as its name would indicate, be used for both divulsion and cutting, and we will now proceed As the meatus is scarcely As it is a fact, however, admitted I think, it on a stretch with this Otis instrument, and withusing the instrument therefore upside down, we now press it down to a point so that when the blade is slightly withdrawn it comes in contact with the first stricture We next, as you see, turn the screw at the end of the instrument and stretch the tissues up to 36 or 37 French, which is shown by the indicator on the end of the instrument We now withdraw the blade for a distance of about one and one half inches, and of course, the urethra being on a stretch, divide all the strictured tissues. We now turn off the tension from the instrument and slip the blade back so it is again concealed, and pass it on down to the other stricture and use the instrument in the same manner as before We next turn off the tension, allowing the two divulsing blades to approxi mate each other, slip the cutting blade back where it is again concealed, and attempt to withdraw the instrument, but we find that we are unable to do The reason of this is that some of the mucous membrane of the urethra has become engaged between the two divulsing blades of the instrument as they approximated each other, and to remedy this we simply again separate the blades slightly by turn ing the screw at the end, and the instrument, as you see, is withdrawn with ease A No 22 English, which is about 36 French, we now find passes of its own weight into the bladder As the hemorrhage is insignificant nothing further is at present required You now see that, for the time being at least, the contractions of the urethra have been entirely removed

It now remains to look after the after-treatment properly, which is as important to the ultimate suc cess as the operation This will consist of passing a full sized sound, which in this case is the sound we have just passed (22 English), about every third or fourth day, until the parts have become completely healed, which generally requires from one to two months For the first few times the passage of this sound will cause a certain amount of pain, but it will be seen that by persisting in the constant use of it until the parts are entirely healed, the complete calibre of the urethra must be restored, and once being restored in such a manner that there is no contraction whatever remaining, there will very rarely be any subsequent contraction In the meantime the patient should receive such internal remedies as are indicated from time to time We will prescribe for the present the citrate of potash, in quantities sufficient to render the urine neutral or alkaline, and therefore less irritating to the urethra than if it were highly acid in character

EXPERT TESTIMONY

Read in the Section on Medical Jurisprudence, at the Thirty
Eighth Annual Meeting of the American Medical Asso
ciation, June, 1887
BY JOHN GODFREY,

SURGEON U S MARINE HOSPITAL SERVICE

"To know facts, to separate them from supposition, to ar-

range and connect them, to make them plain to ordinary capacities, and, above all, to point out their useful applications, should be the chief object of ambition "—WILLIAM HUNTER

There is no intention in this paper to indulge to any degree in a legal criticism of the subject about to be presented. The question as to what constitutes an expert witness, what constitutes expert testimony, and what testimony constitutes evidence, what sorts of testimony are admissible, and what are not, and many things besides, germane to the subject, will be omitted, since they belong more strictly to the purview of the law

The most that will be attempted will be to present a few reflections upon the moral aspect of the subject proper in its relation to members of the medical profession For this two reasons are offered is that, from the structure and behavior of society, medical men are called as expert witnesses more frequently than those of other professions, perhaps as often as all of them combined, the other, that current medical literature amply shows that some features of the subject are yet in an unsettled, and, it may be added, an unsatisfactory state may be added also that, much as medical men are accused of differing among themselves in regard to the particular feature of compensation, they seem to be more unanimous than are those who render decisions thereupon in courts of law

Leaving the decisions to the courts, because, for-sooth, we have to, it may be remarked that, judging from extracts and editorial comments, this one feature appears to be about all of the question that interests the medical world. Nevertheless, it does not follow that it is the most important part, and one feels safe in saying that whatever of time serving sentiment may show on the surface, there is, among those whose high vocation is medicine, an unexpressed conviction that aiding the Commonwealth in its efforts toward the production of universal good citizenship is better work than mere worldly acquisition

As to the competence of expert witnesses it has "That an expert must have special been decided and peculiar knowledge or skill, is as definite a rule as that the search for a lost paper, or subscribing witness, must be diligent and thorough " As all know, the possession of the necessary qualifications is a matter to be determined by the court, yet, notwithstanding the expert witness may be subjected to a preliminary examination in order to test his competency, a recent writer on expert testimony has this "An examination of the cases in which the courts have passed on the competency of experts, shows a lamentable confusion and mixing up of mat ter of fact with matter of law It has been judicially commented on as leading to most unsatisfactory results, and unnecessarily obscuring the true aspect of the law on this subject by the diversity of practice which has prevailed in the judicial tribunals." The Supreme Court of Indiana says "We find no test laid down by which we can determine with mathematical precision just how much experience a witness must have had, how expert, in short, he must be, to render him competent to testify as an expert "

Judging from these and other remarks of learned judges, at least in commenting upon the competency of medical experts, it would seem that they have ap plied the test with anything but "mathematical precision," since they have expressed estimates ranging from the highest to the most satirical and derogatory Take the following as instances

"It was said by The Supreme Court of Illinois a distinguished judge in a case before him, if there was any kind of testimony not only of no value, but even worse than that, it was, in his judgment, that of

medical experts "

The Supreme Court of Texas medical men are received with great respect and con-

sideration, and properly so "

"The experi-The Supreme Court of Michigan ence of courts with the testimony of experts has not been such as to impress them with the conviction that the scope of such proofs should be extended"

The Supreme Court of Pennsylvania settled that the knowledge and experience of medical experts is of great value in questions of insanity"

The London Lancet quotes The Scotch Courts "The evidence was as un-Lord Fraser as saying It left on the mind satisfactory as any he had seen the distressing impression that the science of medicine was simply the science of guessing and experts Different doctors, with equal confidence and equal dogmatism, expressed contrary opinions upon the same condition of things He advised the jury to exercise their common sense, throw overboard the

medical opinions, and go by the facts"

Evidently, from the foregoing, the Justices have had to do with witness material of the most diverse kinds, or else they reached conclusions by very different mental processes But admitting difference in the quality of witness material does not explain the discrepancy in the estimates of the courts, bearing in mind the quotation cited above, that "an examination of the cases in which the courts have passed on the competency of experts, shows a lamentable confusion and mixing up of matter of fact with matter of law" However this may be, at any rate it is the work of jurists, and shows that medical men are not the only ones given to "mixing up" in matters But it does not follow that expert testimony is bad on account of the ipse dixit of a learned judge, for it has happened more than once that an estimate to that effect in a trial court has been reversed in the Opposite opinions, you see, in regard court above to the selfsame thing Nevertheless, whatever the cause, the history of expert testimony is such that, so far, it has not been able to gain a character alto-For this there are various gether above disrepute reasons, some self-evident and in no need of mention, others by no means hard to fathom, but only apparent to close scrutiny The following from "Taylor on Evidence" may be adduced as part explanation in one direction

"Perhaps the testimony which least deserves credit with a jury is that of skilled witnesses These gentlemen are usually required to speak, not to facts, but to opinions, and where this is the case, it is often quite surprising to see with what facility, and to what know what those points are? How many possess

an extent, their views can be made to correspond with the wishes or the interests of the parties who They do not, indeed, wilfully misreprecall them sent what they think, but their judgments become so warped by regarding the subject in one point of view that, even when conscientiously disposed, they are incapable of expressing a candid opinion zealous partisans, their belief becomes synonymous with faith as defined by the Apostle, and it too often is but the 'substance of things hoped for, the evidence of things not seen '"

Herein are foreshadowed two difficulties, one at "The opinions of tributable to inherent deficiencies in human nature, the other growing out of improper methods of obtaining testimony, for surely if one, "though conscientiously disposed," be incapable of "expressing a candid opinion" through zealous partisanship, un questionably he has no business in the witness box, and the ends of justice must fail till such means be devised for obtaining testimony as exclude the ever-

cise of this human failing

But these are not the only difficulties that beset To begin, the breadth and depth of the subject knowledge presupposed on the part of a medical expert is far greater than that essential to the compe-It is safe to say that not tency of other experts one man in ten thousand is endowed with sufficient mental capacity to master all the branches of medi It is safe to say that no living man can cal science truthfully proclaim himself such a master that thoroughly masters even one is justly entitled to, and is cheerfully tendered, the high regard of his professional brethren If the range of purely medical knowledge is so wide, and so difficult to compass, what must it be when further widened by forensic medicine? Undoubtedly it would be better for the State—for the world at large—if every medical man knew all the minutiæ of medical jurisprudence, and stood ready to meet the man of law at every turn, but if, fortunately, he happens to have received some insight into its general principles during his student days, what likelihood is there, while charged with the daily care of patients, or while searching for the secrets of a science that yields at best but grudgingly, that he will trouble his brain with outside studies except in a perfunctory way? Soberly, the problems that daily confront the medical man, plus the drudgery of professional life, leave him but little time to think of, and indeed unfit him for, the intricacies of But admitting the time and the legal questions ability, it is not unlikely that the ardor of the American mind, at least, would be dampened somewhat by the American interrogatory-will it pay? bono is still a common inquiry, and the element of personality is rarely absent from the question advancement must be behind the action of everyday Only the exceptionally great follow promptings from within regardless of reward

In Taylor's work on "Medical Jurisprudence" there are laid down for the guidance of physician or surgeon called to a case of murder or poison some twenty or twenty five points to be nicely observed before the visit is ended How many medical men the detective instinct and training necessary to utilize them? How little likely that a physician, stopped while puzzling over the untoward aspect of his last case, and summoned to a person in the article of death, or about to be, from violence, will pester himself with these two dozen and odd observations in the interest of future legal proceedings? Very few. notwithstanding the caution of a learned judge that "a medical man, when he sees a dead body, should notice everything," and notwithstanding it has been said that "the great art of counsel who defend persons charged with murder or manslaughter, consists in endeavoring to discover what he omitted to do" Certainly he ought to notice everything when he sees a sick body, but how often does he, although the influences are more direct, where the fruits may be seen, and the rewards approximately calculated?

Rules bearing upon facts in medicine, like gram matical rules, are oftentimes overshadowed by ex-This is unfortunate, to be sure, but those who pursue a science should not be blamed for its intricacies Medicine is not a fixed science, and perhaps will never be, though even the most intelligent laymen pretend to think so, consequently the medical opinions of the wisest and most fair minded must en necessitate be dependent in some degree upon the cast and quality of his brain tissue In questions outside of fixed science, so long as brains differ, so must opinions, and in spite of the utmost zeal to

speak truth

In spite of profound thinking and the most industrious research, in spite of centuries of effort to probe the secrets belonging to life in health and disease, in spite of wonderful discoveries and vast advancements, the whole domain of medico legal investigation is yet a wilderness of uncertainties Turn whichever way one may, the exceptions outbalance the In the matter of poisons, vis viva, constitutional resilience, idiosyncrasy, drug habit, in short, any number of peculiarities, leave the basis for evi dence covering very wide limits Sulphuric acid does not always corrode the mouth and fauces, oxalic acid does not always cause pain Arsenic some times gives rise to nausea and diarrhœa, and intense agony, sometimes to collapse and sleep, as if from opium A man dies from tasting tincture of aconite A woman lives four hours after taking 70 minims Immediate ante-mortem violence differs scarcely from immediate post mortem violence Slight wounds of the brain sometimes cause speedy death shot through both hemispheres has survived twentynine days And so on, to a tiresome extent, through out every department of medical knowledge, the exceptions are spread over as wide a field as that between the ages for the beginning and the cessation of menstruation—say from 12 months to 99 years

There is some excuse, therefore, for the medical man, and it is not entirely his fault that it has been said of him that his "appearance in the witness box is but too often the signal for sport among gentlemen of the long robe "

Let it be understood that all along reference has

nor shirking, only desiring to see the right prevail For the medical smartlet, saturated with self importance, noising his opinions that cunning attorneys may utilize them, nosing opportunity for notoriety, scenting the chance to vex or vanquish a professional rival, deluded in the belief that his knowledge is above judge or counsel—for such a one it is enough to say that the worst treatment he gets is better than he deserves The lawyer in search of testimony to fit a special case never fails to find him. The spectacle of a medical man—a man engaged in the highest of all callings-ventilating his opinions, and crowding himself into notice as a desirable witness. for either plaintiff or defendant, is a spectacle that, to the credit of the profession, is not often seen, yet nevertheless seen too often for the profession's good No better than the smartlet is the medical man in the pay of a corporation, when he stoops to coach lay witnesses in suits for damages, putting aside his high vocation to play the rôle of partisan and accomplice But for these it would never have been said from the "The custom of indiscriminately summoning medical practitioners of all sorts, and of all degrees of pathological knowledge and forensic skill, has sadly depreciated the value of medical evidence in courts of justice "

This is by no means flattering, but clearly it is the fault of the medical profession In suits involving medical testimony outside of absolute facts, it is customary for counsel on both sides to go on voyages of discovery in search of medical witnesses to meet special demands And the history of the courts affords ample proof that the counsel rarely fail to find what they seek A distinguished criminal lawyer has told the writer that it is the attorney's rule not to open a trial without knowing beforehand what the medical experts on his side will testify to Is this as it should be? Is the threadbare argument to be offered, that lawyers are entitled to know in advance how certain opinions will affect the cause of their clients? Hardly, if justice be the first consideration It might be said that this would sometimes cripple the proper execution of the law That is to say, it would tend to the excluding of testimony in certain cases necessary to

But the reason, to begin, is not a good one Counsel are no more entitled to previously question a medical man in the interest of clients than are the heads of families before calling him to a case of sick-But, it may be asked, what if one should possess special learning, and felt that his opinion would prove of great value in a given case? No doubt plenty of doctors have the same sort of feeling in regard to given cases of sickness, no doubt some of us have felt that if we could only be called to the case that our brother has been visiting so long, we could bring it around in short order, but the ethics of the profession forbid any volunteering, and the patient gets along quite as safely with the other doc-This rule would work just as well applied to expert testimony as to medical practice, the dignity only been made to those of the medical profession of the profession would be enhanced, its ethics that go to the witness box unbiased, neither seeking | broadened, and justice be none the worse off Adopt

bring the guilty to punishment If so, for the same

reason, it would quite as often save the innocent

it, and there would be no more previous quizzings, no legal coach, no putting of hypothetical questions with the triumphant cognizance of satisfactory forthcoming answers, no "cross and piles" swearing, no laughing-stock doctors, no casting out of medical testimony and striking of balance-sheets by juries Moreover, the vexed question of expert fees, about which there are so many opinions and so many rulings, will have made several strides toward solution

The medical witness that has made himself "solid" with counsel on one side of a case, may urge that his "professional opinion"-"his hard earned knowl edge"—entitles him to professional compensation, but when, being through with the cross examination and from under the fire of the lawyers, he hears his opinion offset by that of another "solid" on the other side, and finds that his testimony is not to be accounted evidence, he may possibly have some misgivings as to what constitutes a proper quid pro quo

The last sentence is not meant as a direct argument against charging professional fees for expert The question as to whether it should be done is still an open one, with decisions on both sides, and apparently of late with a leaning of the courts toward the side of the medical man's doing it Reports of various trials throughout the country show pretty conclusively that the majority of the medical profession inclines to this side, and the reasons therefor—always the same, and unnecessary to give—seem to be self satisfying On the other hand there are others—equals of the best—who think dif-They claim that medicine is not a trade himself to cure the malady for so much in advance but a mission, that he who espouses it takes upon himself the obligation to heal the sick and preserve sional attainments and the stamp of manhood that life, to sustain right and combat wrong, leaving the he bears about him, is summoned to testify uncomquestion of emolument for after consideration They say that to stickle for a fixed consideration in dollars and cents when crime is to be punished and justice to be rendered, is opposed to the most sacred traditions of the healing art, and contradicts the exoteric pretensions of its followers, that the outward avowal of the votaries of medicine is to stand by the weak and assist the needy, if needs must, without money and without price, that the medical man so com pacts with his Alma Mater, that compacts made should be kept, and that he no more than a missionary, should stop to count the cost when good is to be They reason that the Son of Man so taught, that it was implied in the advice to take no thought IROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, COLLEGE OF THIS SICIANS for the morrow, and in divers other teachings, that these teachings, although not at one with the utilitarian instincts of succeeding ages, have been accepted as coming from the Source of all wisdom by such numbers as count far into the millions, and that acceptance presupposes belief, and belief demands practical exemplification In fine, that in all ages of the world the best work of every kind has been done without hope of other reward than that arising from the consciousness of benefiting humanity

These claims may be regarded by many as farfetched, and little better than vagaries, antagonizing the cut-and-thrust tendencies of civilized life, but quently observes that an overstrained eye shows eviwhether they are, and whether they do, at all events, dence of irritation and congestion of the anterior they are not over pretentious in professing to be de- part of the globe or lids By an overstrained eye is

duced from valid premises It should be added, too, that those who make these claims are imbued with no exaggerated notions of sentimentality, and have as few communistic leanings as the most hard fisted individualizer in the profession Nor, no more than the rest of us, do they believe the millenium to have come, understanding full well that man must live by the sweat of his brow, and that a return for services rendered is one of the essentials to the well doing of the race In short, they say strip the subject of all declamation, and let those that write Doctor Medi cinia after their names, declare whether they are engaged in a trade or a mission, whether the business of life means bargaining, or trusting to such emolument as enlightened communities are willing to give for work well done

The solution of the question of extra fees for expert testimony will not be attempted, seeing that in any event it must hinge upon opinion—the opinion of the courts, and the prospects of unanimity among them is still a long ways ahead Instead, and in conclusion, two propositions are submitted with a reasonable confidence in their fairness

- In medico legal cases, if men who practice medicine and surgery are willing to sacrifice professional dignity and cheapen professional knowledge by committing themselves beforehand as to what they would testify if called upon, then they ought to be content with such pay as the law chooses to allow, for, indeed, they are very nearly on a level with the "irregular" who, after hearing the symptoms described, obligates
- 2 If a medical man, on account of his profesmitted in any sense, then he is entitled to such honorarium as his time and talents usually bring him, and it safe to say that such a man will ask no more than he rightly deserves

THE CAUSATIVE RELATION OF AMETROPIA TO OCULAR DISEASES

Read in the Section on Ophthalmology, Otology and Laryn-gology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY JOHN E HARPER, AM, MD, AND SURGEONS, CHICAGO

In calling attention to this subject the writer does not desire to create the impression that he has anything purely original to offer The relation of refractive errors to diseases of the eye and its appendages has been considered in communications from some If, then, he only succeeds in of our best authors adding corroborative evidence to what has already been written, and in drawing forth an expression of opinion from those in attendance, he will have accomplished his aim

Every one engaged in treating ocular diseases fre-

meant one whose accommodation has been taxed to an unusual extent When we consider the direct relation between the nerve supply of the ciliary mus cle and that of the eye and lids, it is very easy to account for the results just mentioned by what is If the straining of accom termed reflex irritation marked congestion of the ocular and palpebral conjunctiva, we can readily understand how important a rôle this would play as a factor of disease when conditions are present necessitating almost constant

Time will not be consumed in repeating clinical facts in this connection that have already become Your special attention will be directed to the influence of accommodative strain in maintaining some of the common forms of chronic disease While the following remarks are also applicable to upon conjunctival and cornerl affections noted and considered in the treatment by most prac- in such cases that not sufficient importance is attached to it doubtedly there are many cases due to this or other causes that pass into the chronic stage before being controlled and the over-sensitive ciliary muscles up sufficient irritation to counteract all ordinary

As illustrating this point three cases will be cited from the writer's practice

Case 1—H M P, at 36, of Newton, Ill, presented himself in October, 1882, and gave the fol lowing history For nearly twenty years he had been a sufferer from granular conjunctivitis associated with pannus During these years he had been treated by many physicians and used nearly every patent nostrum that came to his notice The result of the variety of treatment was in most instances temporary improvement, but whenever he attempted to use his eyes the old trouble returned To use his own ex pression, "during all these years I have not been able to attend to my business properly for one month at a time on account of my eyes"

Examination showed the usual appearances of the conjunctiva and cornea found in such cases Vision was $\frac{20}{100}$ in right eye and $\frac{20}{200}$ in the left Photopho bia was marked and the tears flowed freely when the

eyes were exposed to light

Treatment consisted in the use of a solution of atropine (gr 1v-31) every three hours during the day, and the free bathing of the closed lids with hot After two weeks use of the atropine his cor nee cleared up sufficiently to allow the correction of his compound hyperopic astigmatism. Vision at this time, with the correcting glasses, was R E = $\frac{20}{40}$, $L E = \frac{70}{70},$

The patient being called home on urgent business, passed for a time from observation On leaving he was advised to wear his glasses continually, use atro

taining hyd ox flav gr iv, vaseline 31 ceived from time to time indicated satisfactory progress, and within six weeks after returning home he was able to keep his books and look after a fairsized lumber business

About eighteen months from the time of his first modation for a reasonably short time will produce visit he again presented himself. He stated that he had not lost a day from his business on account of his eyes for fifteen months A test showed his vision to be 器 in R E and 器 in L E The patient was seen last about two months ago, and he informed the writer that he had had no relapse, his vision in each eye was 20, and no difficulty was experienced in reading or doing work requiring vision at close range

Case 2—S M G, et 32, of this city, made his first visit in June, 1883 He had been under treatment most of the time for nearly eight years for granular conjunctivitis with slight pannus diseases of the lids and iris, more stress will be laid gentlemen who had treated him were men of ac-Among knowledged ability, and the graphic description he the recognized causes of simple acute conjunctivitis gave of the methods employed showed that they had we find ametropia mentioned, and while this may be skilfully used all of the standard remedies applicable In fact, nothing seemed to be left for titioners, the writer's experience leads him to believe the writer to try, as the list embraced everything from Un- the silver stick to jequirity Upon careful examination the eyes were discovered to be very sensitive to light and exercise, tearing freely when exposed or used Vision in R E $\frac{20}{10}$, in L E $\frac{20}{50}$ Atropine was used as continue to act, even when not required, keeping in the previous case, and gave much relief from the lachryn ation A test a week later showed the presence of mixed astigmatism which, when corrected, gave vision 20 in each eye

The subsequent history of this case corresponds in the main with that of the first The treatment was very similar, except that mild astringents were employed and continued for a longer period

Case 3 - J H C, æt 22, was first seen September, He was led into the writer's office by a friend, being unable to see his way alone The history elicited was as follows Seventeen months before he had contracted what he supposed to be a cold eyes became inflamed and he immediately placed himself under the professional care of his family phy-Three months subsequently he found his eyes were not improving and decided to consult a specialist of repute Twelve months' treatment under the skilful hands of this gentleman failed to improve his condition, on the contrary, he grew steadily Becoming discouraged again, he decided to seek advice elsewhere

Examination revealed a case of granular conjunctivitis, with marked pannus covering corneæ the second case, nothing was apparently left to be done in the way of orthodox treatment. The eyes, as in the other cases, were very sensitive to light, and although the corner were so opaque that vision could not be tested, the symptoms showed clearly the presence of ciliary spasm. It was decided to use atropine, and the patient's accommodation was brought thoroughly under its influence and kept so for about six weeks Mild astringent collyria were used during the same period, at the end of which pine if the eyes became irritable, and apply once vision had so far returned that it was easy to demondaily to the conjunctival surface an ointment con-strate the presence of hyperopic astigmatism

pine was discontinued for two or three weeks and an week ointment of hyd ox flav substituted The corner continued to clear up, and atropine was again used to determine the amount of astigmatism was not satisfactory, and the correction was post-farticles appeared to be of occasional benefit. The poned until the pannus had further improved

About three months after the patient was first seen the astigmatism was fully corrected, and vision was in the R E 30, and L E 30 The conjunctiva being free from inflammation, the patient was allowed to return home and resume work. When last heard from vision was about normal and no difficulty was experienced in reading

The cases here reported are typical of a large number that have come under the writer's observation, and it is unnecessary to consume time in giving

the history of other cases

Many forms of corneal disease, both acute and chronic, as well as numerous lid affections, have been found to disappear as if by magic when existing ame tropia was corrected

A CASE IN WHICH ABORTION WAS INDUCED FOR UNCONTROLLABLE VOMITING OF PREGNANCY

Read before the Boston Gynecological Secuty, October 13, 1887 BY AUGUSTUS P CLARKE, AM, MD, OF CAMBRIDGE, MASS

I was called on April 30, 1887, to attend Mrs B, aged 32 years, who was suffering from vomiting of Patient menstruated January last, and says she also menstruated March 1, lasting two days Since that time she had had no indication of a return of the menses Until April 30, she had experienced during this pregnancy no unpleasant symptoms The stomach was in fair condition and she was able to take her usual meals

The patient had been married 13 years child, male, was born two years after marriage, that douches were daily employed and occasionally a pregnancy was not attended with any serious symptoms, in fact she was advanced in pregnancy several at night weeks before she was aware of her condition second child, a male, is now 9 years old tient suffered continually during the early weeks of that pregnancy but after the fourteenth week all vomiting and morning sickness ceased The pregnancy continued to full term, and the child was strong and well developed Her third child is now 7 years old, while pregnant with the third child she experienced at first more or less trouble from nausea from the tenth to the fifteenth week but the nausea was controlled to a considerable extent by small doses of ingluvin and bismuth subnitrate Patient [went on without further trouble to the end of pregnancy, the labor was normal and she gave birth to a Within a year after the birth healthy female child of this child she became pregnant but miscarried before the close of the third month She had no morning sickness nor vomiting of pregnancy

terminated December 14, 1881 The patient was a great sufferer from obstinate vomiting from May 21 | not retained, and failed when retained to produce to June 20, that is, from the eleventh to the fifteenth | sleep, and the patient was more exhausted from its

After that date the severe vomiting and nausea were under control During the sickness of that pregnancy ingluvin could not be borne. Iced cham-The test pagne and siphon soda were freely used and these application of a small blister over the fourth and fifth dorsal vertebræ was always followed by a marked improvement in the patient's condition birth to male twins at full term The patient again became pregnant and miscarried during the third month, which occurred in May, 1883, but she cannot now recall that the pregnancy at that time was attended with either vomiting or nausea

At the time I was called, April 30, 1887, the patient had not experienced any special trouble until Other rational and physical signs indithat time cated pregnancy and the patient was confined to her bed and was unable to partake of even the simplest kind of nourishment without nausea or vomiting Siphon soda, iced champagne bisbeing excited muth subnitrate, oxalate of cerium, acetate of morphia in small and repeated doses were prescribed from time to time with only limited benefit ter-irritants to the epigastrium were applied, also small blisters of cantharides to the parts were afterwards applied, these only gave partial relief Subsequently frequent and repeated applications of tincture of iodine to the os and cervix uteri were made These gave the patient a good deal of relief The applications of the iodine were made at intervals of two or three days and sometimes at longer intervals The patient, when I was first called during her last pregnancy, had a very sallow complexion and she vomited not only what food she took into her stomach but she vomited also vast amounts of frothy and catarrhal substances, and also yellow bile urine was heavily loaded with amorphous and granular urates and spiculated spherules of urate of soda First | There was no albumen nor urinary casts Hot-water third of a grain of morphia in suppository was used Gentle laxatives were occasionally used Her and at length the complexion and general appearance

Though the patient was unable to retain nourishment for any considerable period, she appeared to hold her ground until May 27, when she was seized with a severe attack of sick headache, a malady from which she had suffered at intervals since childhood This attack was a great shock to her nervous system The patient was chilly and vomited and suffered from The extremities were deathly cold extreme nausea and the system only partially responded to stimulating applications and to artificial heat to the surface An application of menthol to the head of the body and to the epigastric region, and morphia internally, which had afforded so much relief before now failed The usual solution of cocaine could not be borne by the stomach or afforded no relief applications to the cervix uteri of course had to The next pregnancy began March 9, 1881, and be discontinued and chloral hydrate, which has been often recommended was given in enemata but was

the eyes sunken, and the patient's condition was now means as was the bougie cases, also failed her, and could not be retained by ence was experienced by its presence the stomach nor by the rectum

had attempted to swallow. She was also unable to was the occurrence of an intermittent pain. Anretain enemata of beef peptonoids, or of other nourishment. Dr. Wellington reviewed the plan of treat ary measure against subsequent hæmorrhage. dilate the os and cervix before commencing the ap plications of the tincture of iodine Dr Wellington examined the cervix and made a further attempt at that visit to dilate according to the method of Copeman, but before he had accomplished much he found it necessary to desist, as the patient grew faint He advised that I should make another trial that evening to dilate the os and cervix I did so, but the attempt was only partially successful

The next morning it was very evident that unless the uterus could be speedily emptied the patient

would not survive much longer

The question of inducing abortion we had considered at our consultation, and we also considered that digital dilatation would be a step in aid of that accomplishment But there was another question to be considered, namely, the danger of hæmorrhage, as well as that of shock, and the possible occurrence of has improved, there is less sediment septic influences The question of medical ethics was easily eliminated as the prognosis was neither distant nor uncertain unless the last means at our recover disposal were promptly resorted to At 8 A м, June 4, I placed the patient in Sims' position, and having thoroughly carbolized a No 14, French scale, bougie, olive tip, I inserted it into the cervix in a spiral direction across the fundus between the uterine wall and the membrane so as not to do violence to the latter The bougie was left there for eight hours, and was retained in its position by carbolized cotton tampons The vagina was washed with a solution of carbolic acid (r to 40) before the insertion of the bougie

On the afternoon of that day the patient had a slight show of blood from the vagina, and at 6 PM I removed the tampons and bougie, thoroughly disinfected the parts, dilated the cervix somewhat with the uterine dilator and then introduced a small cu

The pulse was small and the heart was weak, one was bent, and retained in position by the same This was retained until 7 evidently extremely critical R & C's powdered A M, following, when it was removed, together with beef pentonoids, and Wells, Richardson & Co's lac- the tampon, as I had directed the nurse to do if pains tated food, which have proved so useful in other or flowing came on, or any considerable inconveni-

At my visit at 8 30 A M, the next day I again dis-Dr W Wellington saw the patient with me, in infected the vigina, dilated the cervia, and introconsultation, 12 M, June 3 She at that time was duced the curette to see if there was any obstacle to utterly prostrated, she could return absolutely noth-the free exit of the fœtus when it should descend ing in the stomach. She had comited the night be- There had been no flowing of consequence, and the fore sixteen times, frothy substance and whatever she only indication that the patient would soon abort

ment, and remarked that the ground was pretty well. Soon after my visit the pains increased, and by 11 He regarded her pulse as very feeble, but AM, that day, a feetus four inches in length was exsuggested we should make another effort to give the pelled The funis was small or thread like There nourishment in a teaspoonful quantity, regularly as was no marked flowing after the expulsion of the could be done, every twenty minutes, and if that feetus, indeed there was no hemorrhage of imporplan failed, and the stomach refused to retain it, to tance at any time. A large fatty placenta was ex try again the method by injection Dr Wellington pelled twenty four hours after the expulsion of the suggested that digital dilatation of the cervix uteri feetus, and forty seven hours after the bougie was inshould be tried, though I had previously attempted to serted into the uterine cavity-for the first time. At no time after the insertion of a bougie was there any increase of temperature, and no chills, and no constitutional disturbance, in fact the patient began to improve as soon as the fœtus was expelled, and was able almost at once to retain by the rectum repeated doses of beef peptonoids and other nourish-

The stomach gradually grew stronger and by June 12, the patient began to take some nourishment by the mouth, and at no time after means for inducing abortion were adopted was there the slightest increase of temperature or the occurrence of any constitutional symptoms

June 14, 10 AM, temperature still slightly sub-Stomach has retained some thin gruel Patient still looks sallow but is improving Pulse go There is no odor from the vaginal discharge Urine Patient took an enema and had a small evacuation of the bowels Patient feels encouraged and now thinks she will

After this the patient continued to improve and

went on to an uninterrupted recovery

The question is often asked, what is the cause of uncontrollable vomiting of pregnancy? Does it depend upon uterine displacement, local lesion, or an undue constriction of the cervix? Many cases ap pear to be reflex, and treatment directed towards the lessening of reflex action often yield favorable results Vomiting of pregnancy resulting from local lesion, as well as displacement, often occurs, and the vomiting is only controlled when we direct our treatment to the removal of these etiological factors Cases occasionally occur like the one here reported, in which no etiological factors can be discovered, however diligent our search be extended In the majority of cases rette to see if all was clear On removing the boul of vomiting of pregnancy my own observations lead gie I found that it was somewhat eroded I next me to assign as the cause of such sickness the same introduced a No 14 platinum probe, olive pointed, factors as has Professor Graily Hewitt, of London, to this was passed in the same direction as the other uterine sickness in the non pregnant state. Professor Hewitt says that the reflex symptoms of uterine sick- the galvano-caustic loop, was microscopically examness are dependent upon abnormal conditions of the ined by Drs Biesiadecki and Scheuthauer, then asuterus, "consisting of undue softening, congestion and alteration of shape—all more or less associated "

these several abnormal conditions of the uterus are often varied and that such existence, either separately or even in conjunction, may be so slight as not to be recognized by their local manifestations, and that treatment directed to the relief of one of the abnormal conditions may militate against the lessening of reflex irritation emanating from the others Mechanical treatment of the displaced uterus when properly carried out often yields, as said before, happy results, but cases now and then occur in which the displacement or flexion is easily removed though the nausea and vomiting still persist to an alarming extent have notes of a case that came under my care, and though the flexion was controlled, vomiting continued until the close of the pregnancy

MEDICAL PROGRESS.

CURE OF EPITHELIOMA OF THE LARYNX -- Pro-FESSOR SCHNITZLER has recently published, in the Internationale klinische Rundschau, of November 20, 1887, a paper on the diagnosis and treatment of endolaryngeal new growths, in his paper he records the case of a woman in whom he had destroyed an epithelioma of the laryny by the galvano caustic method twenty years ago, and who was still living The diagnosis of epithelioma had at the time been fully confirmed microscopically by very competent and trustworthy pathologists He was nevertheless afraid that, on hearing the case, some might be disposed to make the usual comment referred to in the "Cancer is infollowing remark of Ducarcques curable because it is not cured ordinarily, it cannot term is meant a particular form of acute parenchymbe cured because it is incurable, and when it is cured, then it did not exist " The following are the E L, an actress of Prague, 20 details of the case years of age, was in January, 1867, admitted into the clinic of the late Professor Turck, of Vienna, for persistent hoarseness Turck stated that vegetations of the vocal cords were the cause of the voice Repeated operations performed by him with the knife (in February and June, 1867) were only temporarily successful came, some months later, into the clinic of the late Professor Oppolzer, she was almost absolutely aphonic, and also complained of considerable difficulty of breathing Schnitzler, who was then assistant to Oppolzer found that the local cords were ing of numerous red, non-elevated, and non-irritating much swollen, and detected the presence of red vegetations of a granular appearance at their inner side The vegetations almost filled up the rima glottidis In spite of the youth of the patient, Schnitzler diag- the mouth nosed epithelioma, and immediately removed the neck and the shoulder-blades, and the legs, but not vegetations, which already threatened to suffocate the patient The first piece of a large size (of about pains extended to the sacrum and extremities, and the size of a cherry stone) which was removed by a week later the face and right arm swelled, then the

sistants of Professor Rokitansky Both these experts pronounced the growth to be epithelioma My experience further leads me to the belief that | Schnitzler afterwards heard that Professor Turck had also at once made the diagnosis of epithelioma, and that his diagnosis had been confirmed by the microscopical examination of Professor Wedl Schnitzler had repeatedly destroyed the disease by galvanocautery, and was happy to be able to show the pa tient at the meeting of the Imperial Royal Society of Physicians of Vienna on October 16, 1868, as being cured, that is to say, so far as we were entitled to speak of the cure of epithelioma The patient was still hoarse, but her voice could already be distinctly heard, and the dyspnœa had completely disappeared No trace of the growth could be discov ered (Report of the Society of Physicians of October, 1868) The patient remained under the observation of Schnitzler for some years longer, and he thought it possible that she might have lived for ten years after the operation Before, however, he published the case, he wished to obtain exact particulars as to the patient's fate, and, therefore, applied to the physician who had in the first instance sent the patient to him To his surprise he learned that she was still alive, and that the physician had seen her only recently at Prague, twenty years after the laryngeal epithelioma had been destroyed Schnitzler went on to ask if it was possible that such excellent microscopists as Biesiadecki and Scheuthauer could have made a mistake He could not believe this as their diagnosis was quite positive After all, why should not recovery take place after the galvano-caustic destruction of an epithelioma, as well as after its extirpation with the knife? possibility of curing some kinds of carcinoma was, as is well known, admitted by Rokitansky

> PSEUDOTRICHINOSIS (A NEW DISEASE) -By this atous polymyositis, all the muscles of the body being involved in a general inflammation, in the absence of the trichina spiralis Examples of this affection belong to the curiosities of medicine, according to DR PAUL HEPP, of Giessen, who reports a fatal case of the same in the Berliner klin Woch enschrift, No 17, 1887, and who has been able to find very few accounts of any similar cases above title has been selected as a provisional one When the patient till the true cause of the disease can be made out The following is a brief history of Dr Hepp's case A woman, aged 36, of healthy family, married, and having had three children, began to feel ill in March, Then a rash appeared upon the face, consist-1886 There was dryness of the throat and some spots The rash extended over difficulty of swallowing the neck and back, also to the mucous membrane of Severe pains set in over the nape of the the thighs, became swollen During the week the

The swelling of the face, though it pre lasted one day ing of the limbs, which were also very painful pains were not spontaneous, but set in on the least Stiffness was soon superadded, so that the patient had to be fed The pains were of a dull kind, there was slight drawing of the fingers, but no true formication The appetite remained good all the time, there was much thirst, the urine deposited a copious sediment, and the bon els nere rather con Profuse sweats and sleeplessness were also complained of, never headache The muscles were found to be swollen and in a semi rigid condition, not altered by purposive movements joints appeared normal and were quite free from pain

The œdema was peculiarly hard, and barely re tained the impression of the fingers Gentle passive movements could be made without giving pain, but of slight extent only, owing to the contracted condition of the muscles Each arm seemed like a firm cylindrical tumor, so that it was hard to say how far the muscles participated The head could not be raised from the pillow, only a slight rotation was possible Pupils of moderate width, and react well Voice weak, but normal Sensorium unaffected Sensibility to various impressions normal Tendonreflexes perfectly lost in arms and legs, also abdom-Reflex of sole of foot alone preserved On electrical examination the upper and fore arms and the thighs and legs reacted neither to the faradaic nor the galvanic current, the œdema of the legs was not enough to account for this Strong faradaism caused contractions in the muscles of the hands (interosseous and thenar) The facial muscles reacted well to both currents The internal organs revealed nothing abnormal (the spleen was not en larged), but their examination was very difficult, as it gave pain T 101 2°, P 122, small and soft, R 18, regular Diaphragm acted well Urine scanty, * rather dark, specific gravity 1,036, copious urates, some albumen, under microscope, some few cells, but no cylinders

Within a week or two after admission the patient died in a suffocative attack, preceded for some days by gradually increased difficulty of swallowing The temperature rose to 104° a few days before death, there were severe headaches and much burning feel ing in the skin generally

Autopsy by Professor Recklinghausen - A general firm œdema, except on face Fatty tissue deficient, especially over abdomen Subcutaneous tissue moist All the muscles showed a yellowish pallor, with only here and there a few red spots, and resembled rabbitmuscle, they were very moist Left rectus abdom ruptured in upper part Over the lower part of the right biceps brach very bloody ædematous tissue Hæmorrhagic infiltrations over shin Diaphragm

Fluid blood in vena cava Slight redness of brachial vented the patient from seeing for the time, only nerves Lungs large, much congested, a tew pro The swelling of the arms was very jecting spots dry and hepatized Left lung very ersisted all through remaining life edematous. The right pleural cavity held nearly gradual, and persisted all through remaining life codematous. The right pleural cavity held nearly The back pains reached their climax with the swell-five ounces of yellowish fluid with flakes of fibrin, The the left a little turbed fluid Peyer's patches not to be seen, solitary follicles hardly visible Liver large, weight 4 3 pounds Spleen large, pretty firm, weight 9½ oz Lest kidney very large, otherwise normal, full of blood Right kidney converted into a hydronephrotic sac holding a turbid urinous fluid, but no pus The communication with the ureter was very small, but admitted a fine probe Central organs of nervous system presented nothing abnormal, except for an increase of blood, the meninges were very vascular Gray substance of spinal cord slightly reddened White substance of pons reddened Microscopical examination showed the absence of trichina spiralis The muscles had undergone hyaline degeneration, no fatty degeneration present There was no increase of intercellular tissue. The viscera (except the right kidney) and central nervous organs showed nothing abnormal -London Medical Record, August 15, 1887

> GANGRENE OF THE ŒSOPHAGUS -DR WM WATT KERR, of San Francisco, reports the following interesting case

> During the month of May, 1887, J K, a laborer, was admitted to D ward of the City and County Hospital, complaining of weakness, shortness of breath, and difficulty in swallowing. The history of the case showed that the patient had been addicted to the excessive use of alcohol for many years His breathing had distressed him for about two years, but to this he had paid little attention until a short time before his admission into the hospital, when the difficulty in swallowing began to trouble him On examination the patient was seen to be thin and poorly nourished, cyanosis was present, but not in any marked degree In the epigastrium well marked and diffuse pulsation was visible, but palpation and percussion failed to define any tumor The whole area of cardiac dulness was increased, and a regurgitant murmur was distinctly audible both in the aortic and mitral The epigastric pulsation, together with the difficulty in swallowing, suggested the possibility of aneurism of the descending aorta, but this was rendered very doubtful by the inability to define a tumor, and also by the fact that the sensations of the patient placed the seat of œsophageal obstruction at a higher level than that which would correspond to the pulsating area A small esophageal probang was introduced, by means of which the obstruction was detected and overcome with comparative ease

The diagnosis arrived at was aortic and mitral incompetence, with cardiac dilatation The obstruction of the œsophagus was regarded as something quite distinct from the heart disease, and believed to be due to simple stricture from some injury to the tissues, probably by means of some corrosive poison, normal Heart muscle strongly contracted, of good as it is not an uncommon thing for chronic inebriates color, and held a firm clot The right subclavian to substitute mineral acids for alcoholic liquors when vein and the axillary veins held a little fluid blood | the state of their finances renders it impossible to

obtain the latter The treatment consisted in abso lute rest in bed, the careful administration of digitalis, nourishing chiefly by means of liquid food, and the passage of a probing twice in the week for the purpose of dilating the stricture Under these conditions the patient made some slight improvement, the attacks of dyspnæa were less frequent than formerly, although they occurred two or three times per week, and occasionally were so severe as to present all the appearance of impending death, but the esoph ageal obstruction remained unchanged, in fact, the passage of the bougie did not produce even the most temporary improvement, and therefore its cause remained a matter of doubt After he had been an inmate of the hospital for about three weeks the patient died

An autopsy was made by the interne physician, Dr B A Plant, who found all the chambers of the heart very much dilated and their walls thinned, the aortic and mitral valves were incompetent, but there were no signs of anturism The esophagus was entirely free from stricture in its walls, but that portion lying between the pericardium and the vertebre was softened and gangrenous The changes in other organs did not present anything of special interest bearing upon the case, there being only those which are most frequently met with as a result of chronic alcoholism

Was the gangrene caused by pressure on the œsophagus? In the absence of any other cause, and in consideration that the gangrene was limited to that part of the œsophagus underlying the heart, while the cervical portion was healthy, we are inclined to answer in the affirmative, nevertheless, the fact that the pressure must have been very much relieved with every contraction of the heart, and the frequency with which we have met cases of extensive cardiac dilatation, without ever seeing one in which deglutition was rendered difficult, would make us fain discover some other cause than that which was the only one here apparent - Sacramento Medical Times, January, 1888

CEREBRAL ABSCESS, TREPHINING, RECOVERY BARR reports the case of a boy, aged 9 years, who had had an offensive discharge from the right ear for a year, Three weeks before admission into the hospital he was seized with severe pain in the affected ear and side of the head, with a hot and dry skin, and vomiting and drowsiness symptoms continued for four days, the vomiting then ceased, but the pain and drowsiness remained Eight days from the commencement of the symp toms he had a severe rigor, which lasted fifteen He had six rigors before admission to the hospital, and the pain and drowsiness persisted There was a perforation in the upper part of the tympanic membrane, from which pus escaped Firm pressure over the mastoid produced pain Barr dermatic use of antipyrin in painful affections, in opened the mastoid cells by chiseling through the place of morphia, Frankel records his experience in cortex behind the auditory canal, and injected a the Deutsche medicinische Wochenschrift, No 41, weak solution of carbolic acid through the antrum and Hirsch gives a number of cases in the Berliner and tympanic cavity out by the external meatus, and klinische Wochenschrift, No 46, 1887 He used a also in the reverse direction A small quantity of 50 per cent solution in distilled water, a Pravaz

pus and caseous debris was washed out A drainagetube was introduced into the orifice in the bone, and iodoform used as a dressing Twice a day afterward an antiseptic solution was forced through the opening and drum in both directions Two days later he had a rigor, and the symptoms returned Five days later there was a sudden and copious discharge of pus from the ear All the symptoms subsequently became worse, and ptosis of the right upper lid appeared, and it was decided to trephine the skull The middle car was washed out with an antiseptic solution, and the scalp and neighboring parts care fully cleansed with turpentine and methylated A half inch disc of bone was removed from spirit the squamous portion of the temporal, at a point an inch and a half above and half an inch behind the centre of the external auditory meatus dura was opened and turned aside, the brain tissue immediately bulged into the osseous cavity, and rose above its external level A hollow needle was in scrted into the brain, and, after it had penetrated about three quarters of an inch, there was a sudden escape of foul gas, accompanied by a bubbling sound and the escape of some fluid. The needle was inserted a little farther, when pus of an offensive The aperture in the brain tissue odor flowed out was enlarged with a forceps, and portions of necrosed brain tissue were removed. The cavity was then washed out with a saturated solution of boracic acid Pus continued to ooze from the wound, and an aperture was then drilled into the base of the skull, just above the osseous boundary of the external auditory meatus, involving the squamo petrosal suture. The dura mater was here intact It was opened and the abscess reached A stream of boric acid solution was passed through this aperture so as to wash out the cavity of the abscess, and it made its exit freely by the upper opening The current was then reversed Chicken bone drainage tubes were introduced into both apertures, and the parts were thickly covered with boric acid powder and dressed with sublimated wood wool pads The wounds were dressed about once a week The softened brain tissue at the seat of the upper opening in the skull soon presented a mass of granulations, which increased in size and rose into the aperture in the bone, uniting with the layer which formed on the exterior of the The two soon became blended, and cicatrization rapidly progressed The child increased in flesh rapidly, and was at the end of six weeks quite Three months after his admission all secretion had stopped in the ear, leaving a dry perforation be-A vulcanite shield was fitted over the upper aperture in the skull, the lower one having com pletely closed -Archives of Otology, Vol 16, No 2-

SUBCUTANEOUS INJECTIONS OF ANTIPYRIN -Germain Sée recommended, some time ago, the hyposyringeful being injected into the subcutaneous connective tissue The syringe should be immediately cleansed by passing carbolized water through it sev eral times, or it will become obstructed by antipyrin The pain caused by the injections is very slight, and lasts but a few seconds, and as a rule, there is no inflammation at the site of injection

Hirsch records seven cases in which antipyrin was used hypodermatically 1 Woman, et 45, severe rheumatism of ankle and shoulder, half a syringeful of the solution injected over each joint. In three DR ALLEN J SMITH, of Philadelphia, says minutes both joints were entirely free from pain, which did not return 2 Woman, at 22 pains in ankle for twelve days, for which examination revealed no cause Syringeful injected near external malleolus, in three minutes the pain was gone, and did not return 3 Man, et 51, with severe rheu matic pains in the muscles of the head, back, neck and limbs, and with momentary pains in the lumbar region and along the course of the sciatic nerve Patient could not get out of bed, or even raise his A syringeful was injected, in the lumbar region of each side and in the back of each thigh In ten minutes the patient could raise himself with On the next day there were pains only in the calves of the legs, and half a syringeful was injected into each, the patient got up next day Woman, et 43, with severe pains in right breast, right pectoral muscle painful, and movements of right arm painful Syringeful injected over right pectoral muscle, in five minutes the pain had disap peared, and the arm could be moved freely, the pain did not return 5 Severe neuralgia in the temporal region, in a woman, was relieved by one injection in three minutes, subsequent history of this case not known 6 One injection relieved severe gastralgia in two minutes, the pain returned to a slight extent two hours after the injection Bronchial asthma in a woman, had lasted for a week, Half a syringeful injected on each at intervals side of the sternum during an attack, in two minutes the breathing was easy She had no more attacks, at least for three days, when she was last seen

Dr Captain, whose valuable paper in the Bulletin Medical is partly a resume of the previous observa tions of various physicians, including a good deal of matter contained in a graduation thesis by Dr Caravias, states that the solution of antipyrin in its own weight of water, though it may be used hypodermically, is painful, and he therefore adds fifteen parts of cocaine for every 1000 parts of antipyrin With this solution the injection is much less painful than when no cocaine is added The place where have formed thirty minims In dysmenorrhœa, and uterine pain the bismuth salt in dressing the sore generally, an enema (which is to be retained by the

is very strongly praised by Dr Captain, who suggests that every medical man can easily verify its remarkable anodyne power by a few simple trials doses he recommends are somewhat higher than those frequently given, thus he puts the dose for internal use at from 30 to 90 grains, and that for hypodermic use at from 15 to 60 grains -Lancet, Dec 24, 1887

Sub Benzoate of Bismuth as an Escharotic treatment of a phagedenic tendency in several cases of chancroids in the venereal wards of the Phila delphia Hospital, the writer, then on duty as a resident physician, became satisfied of the faulty character of the local measures, in that the escharotics usually employed were too severe for use, except with anæsthetics, and had to be applied too rapidly because of their excessive action Recalling certain characteristics of several benzoates, a combination of that acid with bismuth suggested itself as of possible service, and acting upon this idea, Mr Joseph W England, Chief Druggist of the Hospital, kindly prepared a quantity of the oxy- or sub benzoate Bismuth subnitrate was treated with nitric acid, heated and dissolved To this, hot water in small quantities at a time was added until a maiked opalescence was obtained, and the solution thus prepared added slowly and with constant stirring to a solution of sodium benzoate in water precipitate was collected, and washed with alcohol to separate any free benzoic acid or sodium benzoate, and then dried The chemical reactions upon which these steps are based, are in Mr England's opinion, probably as follows

BiONO₃ + 2HNO₃ = Bi₃NO₃ + H₂O Bi₃NO₃ + NaC, H₂O₃ H₂O = BiOC, H₂O₄ + NaNO₅ + 2HNO.

In the second equation the bismuth salt is precipitated and the nitrate of sodium and nitric acid separated in the filtrate, in which is present also a quantity of free benzoic acid After drying, a smooth white powder, of a relatively light specific gravity, was obtained This was employed in dressing the chancroids, just as iodoform or other antiseptic powders are used, the sore being carefully cleansed, a little of the powder was dusted over the surface, and the dressing completed with some simple bland ointment For a short time no sensation whatever was experienced, then a warmth of the part, and in about ten minutes a burning and tingling sensation manifested itself and continued for several hours-not severe enough in character to render the patient positively uncomfortable, except the needle has penetrated usually becomes slightly from excitations of the part, which were afterward raised and tender, and once or twice small abscesses controlled by camphor or bromide of potash admin-The usual dose employed by him is istered internally, or by adding a little morphia to

The dressing was renewed once or twice daily, patient) of warm water containing 75 grains of anti and the bismuth powder employed until the type of The action of this the sore had changed—within seventy-two hours in drug in relieving pain of very diverse kinds of origin the three cases under the writer's care, the unhealthy -e g, neuralgic, rheumatic, herpetic, etc, -whether purulent surface becoming clean and red with active given by the mouth, by the bowel, or hypodermically, granulation After this point had been reached

iodoform was substituted for the sub benzoate and the sores allowed to heal, which they did thoroughly and quickly

This material is undoubtedly a mild escharotic when thus applied, with a slow and continued action, and erodes the unhealthy tissues gradually and comparatively painlessly, thus avoiding the inconveniences of such powerful caustics as nitric acid and bromide. It was used as an occasional dressing for indolent leg ulcers with marked benefit, stimulating the sores into granulating surfaces, and cleaning them of the peculiar glazed coating such ulcers often present, just as an occasional application of nitrate of silver would do —Medical News, Dec. 3, 1887

THE VALUE OF TINCTURE OF STROPHANTHUS—DR HOCHHAUS thus summarizes his observations of the effects of tincture of strophanthus

- I For valvular weakness in the stage of compensation disturbance, tincture of strophanthus is an excellent remedy in certain cases, to retard, strength en and regulate the cardiac action The retardation occurs first, while the regulating effect only takes place, as a rule, after a few days Dyspnœa and ædema are promptly relieved. But the favorable effects, in about one half the cases, do not appear with the regularity and safety peculiar to digitalis, and in most cases in which strophanthus failed digitalis was effective Digitalis has, generally, a quicker and more thorough effect, especially in causing diuresis, while strophanthus affects a disturbed respira tion far more favorably It is more difficult to indicate strophanthus than digitalis in cases of valvular weakness, so that it is almost impossible to say beforehand in what cases strophanthus will probably be successful
- 2 In chronic degenerations of the cardiac muscle, with usually a small, frequent, and irregular pulse, great difficulty in breathing and ædemas, tincture of strophanthus may be relied on
- 3 In acute and chronic nephritis the effect of strophanthus is not so marked as in the above mentioned affections. The dyspnæa often yields to its influence as in the other diseases, but the diuresis and ædemas are not favorably affected by it
- 4 In cases of palpitation and apnœa of nervous origin strophanthus often gives marked relief
- 5 Œdemas of a cachectic character may be also favorably affected by tincture of strophanthus
- 6 In some cases the drug has secondary effects on the digestive tract, causing a loathing of food, followed by choking and vomiting after eating, and sometimes by severe diarrhea But, as a rule, the aversion to food is the only disturbance, and this passes off when the stomach becomes used to the drug
- 7 Hochhaus advises to begin with doses of gtt vj, t 1 d, in a tablespoonful of water or wine, and to add gtt 1j daily to the dose until the effect is ob tained, though it is not advisable to give more than gtt xx t 1 d Gtt 1j t 1 d 1s the proper dose to begin with for children, but the doses should not exceed gtt v, t 1 d

8 The effect usually appears on the second or December 3, 1887

third day, and generally lasts a week or two weeks, though there is considerable variation. Hochhaus has never seen a cumulative effect, even after long use of the drug

9 While strophanthus cannot lay just claim to all the praise bestowed upon it, it is valuable as an occasional substitute for and ally of digitalis—Deutsche medicinische Wochenschrift, No 43, 1887

LIGATURE OF THE EPIGASTRIC ARTERY—Injuries of the epigastric artery are seldom diagnosticated during life MARINI reports the case of a man, æt 28, who was stabbed, lost consciousness, and, when he regained consciousness an hour afterwards, com plained of great pain in the abdomen There was but little visible hæmorrhage, but his face and mucous membranes were very pale One of his wounds was in the eighth left intercostal space, penetrating the chest and abdomen, and the omentum protruded The other wound was 6 cm below the umbilicus, and 4 cm to the left of the middle line, and bled The diagnosis of injury of the only when touched epigastric artery was made from the seat of the wound, the free hæmorrhage when its lips were separated, diminution of the hæmorrhage on pressure above Poupart's ligament, and the presence of a considerable quantity of blood in the peritoneal cavity Marini cut down on the artery, and found it completely divided Hæmorrhage ceased when the two A piece of omentum, that became ends were tied prolapsed during the operation, was excised, and the wound dressed antiseptically The other wound healed by first intention, after the piece of omentum was cut off The patient recovered without bad symptoms — Lo Sperimentale, September, 1887

BRAIDED SILK SUTURES IN OPERATIONS FOR LACERATED CERVIN AND PERINEUM—DR J N MARTIN, of the University of Michigan, says I have used silk sutures in thirteen cases with exceedingly good results, and Prof Dunster has used it exclusively for two and a half years with most excellent results I claim for silk sutures

- 1 They are as easily introduced as silver wire sutures
- 2 Easier to tie silk and adjust the parts than to twist silver wire sutures
- 3 Much less irritation to the patient (especially in the perineum) while the sutures are *in situ*, which is important
 - 4 Removal of silk sutures is very much less
- painful

 5 Silk sutures give as good results as silver wire

The hard braided silk should be used for the sutures (about No 10 for the perineum, and a size or two smaller for the cervix), and should be rendered thoroughly antiseptic before and after waxing in bichloride of inercury solution (1 to 800 or 1 to 1,000) or carbolic acid solution. In tying braided silk one important precaution is necessary it is best to make the knot with a triple tie, and the last tie to be drawn down tightly or it may become united —Med. News,

A STATE BOARD OF MEDICAL EXAMINERS

It being admitted that the chief object of laws to regulate the education and practice of the medical profession is to protect the people by enforcing a fair standard of both general and professional edu cation for all who are allowed to practice any department of the healing art, it must be admitted, also, that a competent and efficient State Board of Medical Examiners is a necessary part of all such The education and conduct of the members of the clerical profession are regulated by the Conferences, Presbyteries, Synods, etc., of the several denominations, to some one of which every clergyman is supposed to be amenable, while that of the members of the legal profession is conveniently regu lated by the Judges of the several courts medical profession there are no such complete and authoritative organizations as those alluded to in the clerical, or such reliable and impartial tribunals as the Judges of the several courts for the legal, and consequently some different method must be devised for appointing and perpetuating the desired State Board of Medical Examiners in each State

After reviewing the practical results of all the various attempts to establish boards of censors in connection with medical societies, and State Boards of Examiners by appointment of judges of courts, or by the Governors of States, either on the nomination of State Medical Societies or without such nominations, we are satisfied that no better method can be devised, than to make it the duty of the Governor of the State to appoint all the members of the State Board of Medical Examiners, the same to be approved by the Senate proyided that no possess all the various attempts to establish boards of censors in confibroid tumors of the Paris, this paper, with Dr. W. E. Steavenson Medical Journal, of O. bearing on this subject in that they set forth to a specialty that is too read of Medical Examiners, the same to be approved by the Senate proyided that no possess all the various and by the great expectation.

be eligible for appointment on such Board who was not possessed of a good general and professional education and had been engaged in the reputable practice of his profession at least ten years should be no mention or allusion in the law or in any of its provisions to so called schools or theories in The appointing power should be limited only to the selection of men of known scientific and professional attainments and good character, and the Board itself should have but one standard of requirements and examinations for all candidates who may come before it When the Government, through the agency of its Examining Board, has secured to the people a medical profession all the members of which have given satisfactory evidence of having acquired a good general and scientific education, and a thorough knowledge of all the departments of medical science and practice, it has fulfilled its duty Whether the men or women thus found qualified and registered as legal members of the medical profession shall, in their intercourse with their patients, prescribe a large dose or a small one, or shall select their drugs in accordance with one theory or another, must be left to the judgment and conscience of each individual

It would be a good rule to make the State Board consist of nine members, each holding office three years, but eligible for reappointment. Whether the appointing power should be prohibited from appointing any person holding an official position in a medical college either as an officer or teacher, or whether he should be required to select one member of the Board from the faculty of every legally established medical college in the State, is a question concerning which there may be differences of opinion. Probably the first alternative would meet with the most general approval

ELECTRICITY IN THE TREATMENT OF FIBROID TUMORS

At the last meeting of the British Medical Association an interesting paper on this subject was read by the great exponent of the use of electricity in fibroid tumors of the uterus, Dr. G. Apostoli, of Paris, this paper, with one on the same subject by Dr. W. E. Steavenson, is published in the British Medical Journal, of October i. Two such papers bearing on this subject are particularly interesting in that they set forth the conservative principles of a specialty that is too much, or likely to be too much, an operative specialty

proved by the Senate, provided that no person should electricity to tumors of the uterus has been, in a few

words, to supplant the old methods of operating by a method that is precise, energetic, tolerable, better localized, thoroughly under control, and more scien-He made it precise by the introductifically exact tion of new galvanometers of intensity, exact coun ters and measures of the electric current, energetic by a novel service of high intensities of current, tolerable, notwithstanding the large doses of electricity, by introducing a new form of electrode, the wetted clay, thus making the cutaneous pole harm less, and permitting the transmission through it of a current of signal medical intensity, he localized it better by the direct application of the active pole, through the vagina, to the uterus, either in its cavity or into the fibroid deposits, and he brought it thoroughly under control by the exclusive use of the unipolar method, thus applying to the diseased uterus a continuous galvanic current of sufficient intensity and duration to produce the required effect application, generally inaccurately described as electrolytic, says Dr Apostoli, should be defined as a galvano chemical cauterization-a cauterization purely chemical, with two successive and distinct effects developed in the course of the current First, a tangible effect at the points of entry and exit of the current, which, according to the dose and duration, will be a chemical cauterization more or less severe (but not thermic), variable in conformity with the pole, and different in its character at the two poles At the will of the operator this polar action may be Second, the effect resulting monopolar or bipolar from the circulation of the current from one pole to the other, and therefore called interpolar action an action that follows every electrical application, setting up a subsequent process of disintegration of the morbid products through which it passes

But what are the clinical and purely practical results of Apostoli's method? Before going farther it must be said that the positive pole is the express remedy for hæmorrhagic fibroids, and the negative for non-hæmorrhagic-the positive being a hæmostatic, and the negative producing congestion both in their secondary interstitial action induce a regression of the tumor, Apostoli believes that the negative has the greater potency in this respect Further, if the negative pole be made to enter a fibroid deposit by a puncture, it will insure a more rapid diminution of the tumor, and the negative pole, naturally a congester and but little hæmostatic, finally becomes markedly hæmostatic, and will arrest troublesome hæmorrhage after a certain time, an effect caused by the cutting off of the supplementary circulation, by the rapid atrophy due to the of menstruation, dysmenorrhæa, amenorrhæa, nerv-

action of the negative current For the use of galvano puncture there are certain rules, that may be thus summarized 1 Absolute and regular antiseptic irrigation of the vagina, before and after each 2 Use as the puncturing instrument the operation small steel trocar or needle, and let the punctures be shallow, that is, not deeper than from 1 to 2 cm 3 Make the punctures on the most prominent part of the fibroid, whenever possible in the posterior cul de sac 4 Make the punctures without speculum Slide the trocar through the celluloid sheath that protects the vagina, after having examined and chosen by touch the point where the puncture is to 5 Ascertain the seat of any pulsation, so be made as to avoid wounding an important vessel case of unusual hæmorrhage immediately dilate the vagina with an expanding speculum, and if necessary put on pressure forceps to the bleeding point

In answering the question as to the anatomical and clinical results, as regards the material changes it may be affirmed, says Apostoli, that every fibroid tumor submitted to this treatment, sometimes after so short a time as one month, but certainly when the treatment is fully carried out, will undergo a manifest reduction appreciable by the touch and demonstrable by internal measurement diminution of the tumor, which continues for some months, varying in amount from a fifth to one half of the original volume, is generally associated with a coincident, and equal accumulation of subcutaneous adipose tissue on the abdominal walls regression of the tumor is not only apparent during the time of active treatment, but goes on continuously after it has been suspended, and is the persist ent proof of the enduring influence of the elec-Simultaneous with the decrease trical operations of the bulk of the tumor occurs the liberation of the tumor from its local attachments tumor, that at the beginning of treatment was immovable, is made to change its position more and more as the absorption of the enveloping tissues And with the regression of the tumor is advances a tendency of the tumor to separate itself from the uterus, to become more distinctly subperitoneal, to detach its mass from the uterine wall, and to assume The clinical are not more of a pedunculated form Apostoli less striking than the anatomical results generalizes the extent and importance of these results, by saying that 95 times out of 100 they comprise the suppression of all the miseries constituting the fibroidal symptomatology, which may be thus categorically summarized hæmorrhages, the troubles

ous disturbances, the direct pains in the growth itself and from mechanical pressure, and the harassing And while this theraseries of reflex actions peutical resource carries us so far as the sensible reduction of the fibroid tumors, and not to their total absorption, yet their complete removal may be anticipated, with a complete restoration of health The greater number of the women that persist in the necessary treatment are not only cured, but remain In some of his early cases Apostoli found an apparently absolute intolerance to high intensities of current, and he abandoned the method in these cases, at present he would simply chloroform the patients, and operate to the fullest extent regard to such cases he lays down the following rule No operator should admit the failure of intra uterine galvano cauterization before having had recourse to with or without an esthesia

From July, 1882 to July, 1887, Apostoli made 5,201 applications of the continuous galvanic current, for the following affections Fibroids of the uterus-polypi, entire or partial hypertrophies of the uterus, subinvolutions, acute and chronic me tritis and endometritis, ulcerations of the cervix, peri uterine inflammations (perimetritis, parametritis, cellulitis, phlegmons), ovaralgia, ovaritis and peri ovaritis, salpingitis, ovarian and tubular cysts at an early stage, atresia, and hæmatocele The 5,201 operations were made on 403 patients (this number does not include the patients on whom faradism was used) Of this number he lost two patients, the re sponsibility for which he takes upon himself, as well as of ten phlegmons that he either excited or aggra vated, and in speaking of these he takes occasion to warn against careless use of the method, especially of the negative pole when there is any trace of peri uterine inflammation present "You must feel your way, testing the susceptibility you have to work upon by two or three preliminary operations, in which you give doses so feeble that they only serve to enlighten you, and to habituate the patient, so as to lead on safely to the use of higher intensities "

MEDICAL SOCIETY PROCEEDINGS —We are pleased to receive good reports of the papers, cases and discussions presented to the medical societies in all parts of the country, and happy to publish them as fully as our space will permit Recently some societies have been sending us reports of discussions

comes of the papers or even brief abstracts of them Such discussions, without the papers or abstracts of them, to which those participating in the discussion are constantly alluding, lose half their value and often contain sentences unintelligible to readers of THE JOURNAL We must decline to use such reports

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, October 12, 1887

THE PRESIDENT, JOS TABER JOHNSON, MD, IN THE CHAIR

Dr T C Smith read the history of the case and the galvano punctures, which we must enforce either presented the specimen, for Dr P J Murphy, of

A UTERINE FIBROMA REMOVED PER VAGINAM

Mrs McG, white, æt 40, born in Maryland Admitted to Columbia Hospital for Women, Sept 8, She is married and has had two children, the youngest 13 years old Had a miscarriage from some unknown cause four years ago and has complained ever since of considerable pain in back and hypogastrium, shooting down the legs For the past three years has had a profuse leucorrhœal discharge which was at times bloody and again very watery During the past three months the odor of this flow has been very offensive Menses regular and profuse lasting about four days, the last epoch having been in the latter part of August She has very frequent and severe attacks of intermenstrual hæmorrhage from the slightest causes, the most frequent being excitement, appetite poor, frequent attacks of diarrhœa and of severe headache She presents the appearance of a woman subjected to severe constitutional drain, the face has a pale and leaden hue kept in bed until Sept 11, when she was examined with the following results

The outline of the uterus not distinctly ascertained. but bimanually a large globular growth three or four inches in diameter was found slightly protruding into vagina from the canal of the cervix uteri Its borders could be followed into the cervical canal but owing to the size of the growth its attachments could not be definitely made out The watery discharge is now profuse and has an odor not entirely unlike that of carcinomatous discharges It was thought to be a pediculated fibroid of the uterus although the density of the foreign body was not marked. The odor now became so offensive that the patient was isolated This however was rendered unnecessary by a few hot carbolized douches The urine was not voided freely and it was examined, although nothing other than a

general diminution of salts was found

Sept 17 Dr Jas E Morgan came in consultation and advised early removal of the growth to save the woman's life It was thought best to improve her on papers that had been read, without including either general condition previous to operating and she was

given the following tonic sulphate of quinia, 30 formed October 2, 1887, without chloroform or an grains, tincture of chloride of iron, 4 drachms, to anæsthetic of any kind, and as far as any visible mix and take 30 drops in water three times daily Milk punch every four hours, beef tea, etc days later she had a severe attack of diarrheea accompanied by rectal tenesmus, which however soon yielded to ordinary doses of bismuth and opium

25 Iron and quinia discontinued Gave the following Make 36 grs of ergotin, 2 grs of extract of be sure to get an operation from the bowels, which cannabis indica and 1 gr of strychnia into 12 pills, to take one every four hours Menses appeared on the 28th and lasted until Oct 5, but not so profuse sleeps and nurses well, the stitches are out, and the

as usual although more painful

Oct 6 Growth protruded more and was attached on every side to cervical canal Uterus now felt distinctly and is enlarged, hard and of irregular shape, the lateral diameter being disproportionately increased

8 Patient anæsthetized and the foreign body removed It was first drawn through the vulva (the patient being in the lithotomy position), and its ses sile pedicle which was found attached to nearly the was not one of those that underrated the achieveentire surface of cervical canal and fundus uten, was severed by Thomas' saw scoop, Yarrow's modification, very little hæmorrhage occurred as the hard upon this region of the body when absolutely necesfibrous pedicle was sawn through

The uterus and vagina were washed out by a carbolized douche at a temperature of 110° F, and a pledget of styptic cotton placed against the cervix Some oozing began about an hour after the operation but soon ceased Patient was very weak but improved rapidly after the oozing ceased and is apparently making an uninterrupted recovery tumor removed is globular having a circumference of about 8 inches in every direction and weighs 6 oz

The President read a letter from Dr Alex Dun LAP, of Springfield, Ohio, in which he gives the following interesting case

A LAPAROTOMY ON A FEMALE CHILD NOT AN HOUR

The child was perfect in every respect, vigorous and healthy, except that the bowels, commencing close to the duodendum, down to the sigmoid of the colon and omentum, with the mesentery, dragged through a small opening in the umbilicus, and had been developed in a sac formed in the umbilical cord The sac would have contained about a pound and a I found that it was impossible to return them through the opening without enlarging it, and then when I commenced to enlarge the opening I found that the abdominal cavity was so contracted from medical treatment the absence of the bowels being developed in it that it would not contain them without enlarging it I therefore made an opening, commencing in the umbilicus, running up two inches, and then began stretching the walls of the abdomen with my fingers, then catching portions of the bowels and forcing them down into the cavity, while assistants, with the operation hooks passed through the cut edges of the walls of headache are continuing for three years after the the abdomen, held them firmly up In about twenty operation minutes I succeeded in forcing them in and closing being performed far too frequently, and that it was the wound with five sutures and ligatures to the cord time for the profession to call a half and forbid such close up to the natural skin The operation was per- unnecessary operations

signs were manifested by the child in struggling, cry-Three ing, shock or pulse, that it was suffering pain there was none to be seen For all that you could see the child might have been enjoying the operation hugely, nor has there been the least unpleasant symptom I gave it a small teaspoonful of castor oil to operated freely I have given five or six doses of one-third of a drop of tincture opin cord is separating nicely How long after birth be fore the nerves of sensation are brought into action? They were certainly not in action when I performed this operation

DISCUSSION ON BATTEY'S OPERATION

DR ROBERT REYBURN, in opening the discussion on the case of Battey's operation reported by Dr Jos Taber Johnson at the last meeting, stated that he ments of abdominal surgery, on the contrary he was a firm advocate for the performance of operations sery for the saving of the life of the patient, or for the removal of the ovaries when hopelessly and in The case reported (on examina curably diseased tion of the ovaries removed) showed that it did not belong to either of these two classes, and hence was not a proper case for operation In his opinion the cases properly and absolutely requiring this operation were very rare, and in an active practice of thirty-one years, he had never operated upon a case, nor had he seen one that he considered required it He had, however, witnessed the operation a number of times and the results were, in his opinion, not at -Some of the patients, it is true, all satisfactory were cured, but in a great proportion of the cases the operation was either a failure or followed by periodical pelvic pains, attacks of neuralgia, etc, which rendered their condition as bad as before the operation The technique of operations upon the abdomen had become so perfect, and the risks of the operation so diminished by the improved antiseptic methods, as to induce the performance of an immense number of operations that should never have been In his experience the patients that deperformed sired the operation belonged to one of two classes, either obstinate cases of dy smenorrhœa, or, perhaps, of evil habits, and who required as much moral as He called attention to a paper by Dr Coe, published in the Medical Record, Dr Coe states that he of September 24, 1887 has known severe pelvic pains, neuralgia, flushings of face and other vaso motor disturbances to occur at the time of the former menstrual period, and in these cases their condition was worse than before Two cases of violent congestive He believed that the operation was

the Pennsylvania Hospital for the Insane for recur-|ful rent mania, came under his care about one year after She had previously been under his charge and not having improved she went to that hospital and her ovaries were removed. Success was apparent and she was removed from that institution In a year's time the attacks of mania recurred with their former There was no return of menstruation She came under his care four or five times after this It was near the menopause as she was 40 or 45 years old, but she kept on having the attacks She would improve and leave the hospital, but would return in a month or two as bad as ever The artificial meno pause was produced and her general health improved

Bearing on insanity A young girl, about 12 or 13 year's old, was under his care in 1876 and '77, for about eighteen months Menstruation was not es tablished It was as pure a case of moral insanity as had ever come under his care For sin and in iquity she took the lead, at times the attacks were aggravated, and she was always erotic Restraint was used, anodynes and an esthetics were given, and all treatment seemed baffled Every means of reformation was tried in vain, and the mother's use of the rod was fruitless He lost sight of her She was removed to the Worcester Hospital for the Chronic Insane, under Dr Quimby, whose opinion coincided with his, and she was advised to go home on account of a great aversion to hospital treatment The menstrual function appeared but she became Finally she fell into Dr Goldsmith's hands At a meeting of the Superintendents of Institutions for the treatment of the Insane, Dr Goldsmith read a valuable paper (Journal of Insanity, 1883) bearing on this case Dr H R Stohrer was invited to dis cuss the subject of Battey's operation and he recommended it in this case It was performed and the girl resumed her natural, amiable disposition year after she was perfectly well After such a result he felt anxious to hear from those present the changes wrought in menstrual conditions by the removal of the ovaries Of course we must not be led astray by extreme cases Several cases are on record of the removal of the testicles for nervous derange

DR T C SMITH regretted that Dr Reyburn had condemned the operation simply because it is some times performed unsuccessfully or unnecessarily in one class of cases In other cases it is justifiable A woman has dysmenorrhoea for years and years, she goes from specialist to specialist without receiving any benefit, and after years of fruitless treat What would Dr Rey burn do in such a case? How long would he wait?

DR Godding had come to the Society to learn an extra uterine pregnancy, but she went to term and not to hear an experience that was practically Six months ago he examined the same woman and A woman, who had had her ovaries removed at found the left ovary the size of an egg and very pain-It does not yield to treatment Is this a case for operation? The size does not demand it but the pain is increasing Suppose Dr Reyburn has a bleeding fibroid that has resisted all other treatment would he refuse to establish the menopause by removing the ovaries? Or suppose he has a pyo salping would be permit it to rupture? What would be do in such a case? He should be more explicit

DR REYBURN regretted that he had not been understood He considers the first case mentioned by Dr Godding a clear case of the abuse of the operation (?) A great many operations are performed when the disease does not threaten life. The ovaries are removed when there is no appreciable disease but only the evidence of a perverted function the woman were going about would he remove the ovaries simply because she had a pain in her side? No Such is not a case for operation. If the disease goes on, yes Loss of texture such as to endanger life, and bleeding tumors may justify the operation It is not always justifiable in bleeding fibroids Better dilate the uterus and remove the fibroid Nowadays surgeons and gynecologists must have a few ovaries in their pockets to be fashionable

DR FRY asked, From the history of the case and the specimen presented was the operation justifiable? The speakers had confounded Tait's and Battey's operations The former removed the tubes and ovaries for a pathological condition, and the latter simply to establish the menopause artificially without regard to disease of the organs themselves last meeting of the American Gynecological Society, Dr Polk expressed the opinion that the operation was not called for, Dr Martin, of Berlin, cured his cases by other means, and Emmet let the ovaries After Dr Johnson had loosened the adhesions the operation should have ended and the abdominal wound have been stitched If the operator finds healthy tubes and ovaries he is not justified in removing them The question is whether these cases can be relieved by less violent means In this case the operation was scarcely justifiable and Dr J should have been satisfied when he saw the ovaries were in such good condition with breaking up the adhesions and leaving them

DR KING When the operation was first introduced the dangers were anticipated and stated is too frequently performed where it is not absolutely necessary, but we are all human and hable to err Battey's operation has had its day as a fashionable surgical procedure Years of practice and experience have enabled surgeons to formulate better rules ment she falls into the hands of the surgeon who has for its performance than they had at the beginning removed the ovaries in women similarly affected and At the last meeting of the American Gynecological Society, Battey stated the results of his operations some were not cured, some were only benefited a He has a case that will ultimately call for the removal little, while the majority "bounded like an India-She became pregnant three months rubber ball, into health" Women hear of others after marriage She was suddenly seized with a pain being relieved and go from one surgeon to another in the left side and discovered a lump as large as a until they find one willing to operate, and he probahen's egg She called in a physician who suspected bly removes the healthy ovaries Dr Polk opens the

abdomen, breaks up the adhesions and leaves the at hand. They go from doctor to doctor, undergoing healthy ovaries This is an advance and does not mutilate Some are relieved by time ago Dr Johnson suggested Battey's operation in an old maid She afterwards came under his care was near the menopause, he used Goodell's method failure Of course he had made a mistake but this of dilatation, and she had a delightful relief for two or three months at a time. The loss of the ovaries makes very little difference in those who do not contemplate matrimony, but these organs are of great He does not recommend every ovary to be removed consequence to poor women in whose family there is an entailed estate The most interesting and important question of gynecology is the reason for women having such diseases, as cysts, as to call for such mutilating operations. Have we no means of prophylaxis?

DR KLEINSCHMIDT There is one interesting point raised by Dr King Why do women of this age have cysts and other diseases of the ovaries? They are not more frequent in this age but abdominal surgery has advanced so far that they are easily detected The ancients found diseased ovaries but did not understand them Hyrtl has a work on spaying women an which there is a case of a man spaying his daughter Dr Smith's first case should have received the galvanic treatment and if that failed preparatory laparotomy Twenty years ago, in discussing ovariotomy, he remembers that Dr King advanced the opinion that the time would come when we would be able to tell these growths with certainty It is easier to operate at an early period of the disease ovary in Dr Smith's case is diseased let him find out what is the matter with it

Dr Bermann The question raised by Dr King is an important one. If the women of to day suffer more than those of former times he thought it might be attributed to two causes, viz constipation and tight lacing

DR FRY had had a case under obsevation for six or seven years The woman was 32 years old and one ovary was prolapsed into the cul de-sac would put her into the knee chest position, relieve the retroflexion and tampon the vagina She was She would confined to the bed most of the time get better and the treatment would be discontinued She returned several months ago and he determined He has been using the galvanic to try electricity current about two months, but has also used the She has improved and the ovary is smaller, but he is not certain that the electricity is entitled to He has considered removal of the all the credit ovaries but the woman's family oppose it sometimes die and if one were his he thought his conscience would bother him

DR JOHNSON had not intended to say anything as the members understood his opinion on this subject His views have not changed He has reflected on every case before he operated because he did not The President, S Pollak, M D in the Chair He sees a great many cases but desire to be rash does not operate on half the women who desire to have their ovaries removed In some respects he agrees with Dr Reyburn, but would not take the The majority of women he sees are chronic sufferers and cannot be cured by the means nose and hips being developed to a less degree They

various methods of treatment, but grow worse, Sometime everything fails and they are willing to run the risks of this operation He might operate and the result might not be as good as he expected, or an absolute should not lead him to abandon the operation, be cause mistakes are made in all branches of surgery, and yet they are considered perfectly justifiable Battey's operation is for the removal of the normal ovaries and was called normal ovariotomy operates to bring on the menopause and that was his motive in the case reported It was a matter of dol lars with poor women, many of them are bed ridden for months and have tried all sorts of treatment without benefit and their only hope seems to be in the removal of the ovaries He holds that the operation should not be performed until she has had all the ad vantages of general medicine Give electricity a fair trial He has received letters filled with grateful expressions from women he has operated on who are now enjoying excellent health In a case Dr Ober is now attending the woman was relieved for a time but is now growing worse Perhaps the convulsions are due to a third ovary Of the 54 cases presented by Dr Battey, 33 were cured, 8 much improved, 5 a little improved, and 8 not at all improved these 54 cases there was complete menopause in 50, and continued menstruation in 4 Tate removed the ovaries in 50 and produced the menopause in every Dr Godding's experience case and cured them to is nil, one case did well and the other is cured would remind Dr Fry that Dr Polk did not have everything his way in the discussion referred to Dr Goodell opposed two operations instead of one Dr Bantock agreed with Dr Goodell that the alternative recommended by Dr Polk was not the correct one The operator does not desire to unsex the woman, He has a patient the disease has already done that under observation at present who is sane for three weeks out of every four, but during her menstrual period she is a confirmed nymphomaniac and uses He is in doubt as to the the most vulgar language proper course to pursue Dr Godding's successful case prompts him to operate It is true Goodell's asylum patient died, but the hygiene of the institution may have been bad, and if she had been out she might have been cured If the trouble seems to be connected with menstruation the proper procedure would seem to be to produce the menopause

ST LOUIS MEDICAL SOCIETY

Stated Meeting, November 5, 1887

DR T F PREWITT presented a case of MULTIPLE TUMORS OF THE HEAD

The case is of a gentleman whose head is covered with a number of tumors, some on the forehead, are extraordinary in many respects, and would tax the skill of many diagnosticians. He has had them for twenty five years. They have not impaired his health, but are merely annoying

If there had been only one of these tumors, I would have been impressed with the idea that it was a sebrceous cyst, because it fluctuates distinctly Then it occurred to me But I have excluded that that possibly it was sarcoma, but the history is not that of sarcoma, which is of rapid growth, and pri mary sarcoma of the skin is a rare thing looking at the development on the face and the char acter of the skin, which the gentlemen will notice is muddy, that condition which we so frequently see in young persons subject to affections of the sebaccous glands, it occurred to me that it was in adenomatous condition, that the glands of the skin were involved But that was not entirely satisfactory to me, the tu mors are very vascular and bleed quite freely one which I cut off I had to arrest the hemorrhage with pressure and applied the electrolytic needle Professor Bremer and Dr Rohlfing examined sec tions from it and pronounced it adeno sarcoma great vascularity suggested to me that there was some sarcomatous degeneration, and I expressed myself to that effect The next question is, what can be done? I propose to try electrolysis on some at least, and endeavor to get rid of them, even if reproduced If it was a single tumor I would not hesitate to cut One or two of them have been cut out, and he thinks they have not grown again, but they can be seen to be growing at the base of the cicatrix He does not know how they first came He 15 52 years old

DR A H OHMANN DUSMENIL The disease is not one, because we have in the lower part tubercles, and in the upper part masses undergoing cystic de generation, or through pressure the skin becoming I don't think it fair to ask a diagnosis without giving a specimen for examination look like lipomata, others like fibromata, whilst oth ers have some hardened matter, which may be inspissated sebum or calcareous degeneration of the tis It is not a pure case of fibroma of the skin, as that is generally multiple, and more or less pedun Nor is it lipoma or lymphangioma, which the lower portion simulates. I do not remember a sımılar case There is involvement of the subcutaneous connective tissue

Dr E H GREGORY We understand that these tumors are not growing, therefore these masses are performance wanting in one of the essentials of a tumor, namely, indefinite and continuous growth We do not recognize any overgrowing mass as a tumor unless it grows continuously, indefinitely, and whenever a mass comes under our observation that has existed for months without any material change in its bulk, it becomes a question whether it is a typical tumor or not If we are looking for a cause of these masses, I would attribute it to a vegetable parasite, or some agency of irritation, and I would place it in that class of diseases, the so called granulomata As for adeno sarcoma, that means nothing more than over

tissues, involving perhaps more than one element of The question is, is it an overgrowth after the skin the method of a tumor, or an overgrowth from irritation? I would place it among the latter

DR F I Lutz reported a case of

CUNSHOT WOUND OF THE INTESTINE

The case occurred last Saturday night et 30, was shot by another with a revolver carrying a 38 calibre bullet, the ball entering 34 inch below the umbilious in the median line. He was taken to the City Hospital The abdomen was distended considerably, there was resonance over the liver, indicating that gas was in the peritoneal cavity, a long probe entered the cavity in a downward, outward and backward direction to the right was considerable pain On opening the cavity, we found that very little of the contents of the bowel In were in the peritoneal space, as the intestines were The jejunum had six openings in it, and the empty The mesentery was cut in two places, ileum two and the parietal layer of the peritoneum covering the posterior side of the cavity to the right of the common thac artery had a rent in it which was the beginning of an opening which ran down toward the The openings in the bowel were united with silk (iron dyed) sutures, and the others with catgut The opening of the ileum being so near the mesentery, I concluded that the continuous suture going clear around the bowel would be the most rapid and equally as safe a method of suturing it The bullet was not extracted ante-mortem large blood vessel was wounded The patient died. The openings which had been sewed I found perfectly water tight at the autopsy This is another illustration of what I have endeavored to express on several occasions, that penetrating wounds of the abdomen should be treated with free opening One point in the technique is that the long continuous exposure of the intestines to the air is no mean factor in determining the fatal issue of the cases Perhaps it would be more perfect if some means could be invented to keep the intestines at a proper temperature—and it is necessary to expose them well in order to sew up a rent in them—and the ordinary clothswrung out in hot water cool so rapidly that they have hardly any influence in keeping a proper tempera-In this case we irrigated the cavity with hot Whilst the proportion of recoveries after this operation is small, still it is large enough to favor its

DR Lutz also reported a case of

TRAUMATIC PERITONITIS

The patient was kicked six weeks ago in the left groin, by a cow, and as a result the glands of the groin inflamed and suppurated, and I removed a nest of them I removed those on the line below Poupart's ligament Subsequently several of the glands high up inflamed I made an incision and cleaned out the cavity and united the two incisions by a drainage tube The man's general condition was bad He seemed anæmic, had chills, but never complained of trouble in the abdomen until two growth of the glands of the skin and its connective days before death, nor was the abdomen distended. He was not under the influence of opium and a half before death he had a chill and high fever, his abdomen became distended, very painful, and he the inside of men's bellies in these cases, the more went into a comatose condition, and died 36 hours after I first observed that the peritoneum was in-On opening the cadaver I found a typical case of peritonitis, septic, coils of the intestine glued together with exidate, and a small hole half the thickness of a pencil, ulceration had taken place laparotomy. When there are urgent symptoms that through the wall of the abdomen, so that if laparotomy had been performed in this case, and the cavity thoughly cleansed. I think his chances would have been better

DR LUTZ also reported a case of

LAPAROTOMY FOR TYPHLITIS

The man came into the hospital on Tuesday, he had a tumor in the right iliac region, about as large as an ordinary fist He had had it for several months and it was very painful and tender We had him in the clinic on Wednesday, and after he left it peritonitis set up, which increased and became violent that you can put your finger in thereafter. This morning there was stercoraceous necessarily fatal will be attended to The pulse had been 115 and full, but this vomiting morning it was 100 and full the side, dulness extending to the right inguinal re-On opening it an immense quantity of pus escaped, pus of a fæcal odor The coils of the jejunum and ileum were matted together by evudation, and on the right side the omentum was so firmly bound down in the neighborhood of the internal ring of the inguinal canal that when I felt with the fingers people recover that have extravasation, the result of and found a cavity that contained pus, and this was gunshot wounds of the intestines I have yet to see so firmly adherent, I thought that there was in addition a strangulated hernia However, I could pull intestine that is agglutinated and shut up On the it out readily, and we washed it with a flush of hot water We found a knuckle that was the point strangulated, a part of the gut bent on itself and united by exudations, and glued to the anterior abdominal wall in front of the bladder There was considerable bleeding, caused by the separation of the intestines necessary to find the strangulated portion patient died, as we expected I believe it was one of those cases in which an early operation would have given him some chance. If it was a perityphlitic abscess at first, a lumbar incision might have Perhaps these operations are not trisaved him umphs of the surgical art, but they teach valuable The first the lack of proper appreciation of the surroundings of the case, the lack of masterly The third indicates that early incisions should be made to prevent complications such as came up in this case

DR E H GREGORY presented by the first case before the operation?

strong, temperature good, the abdomen was distended, then-which to me was the best indication of what should be done—the probe passed to such forming laparotomy, allow him to die in peace a distance into the peritoneal cavity There was no fæcal matter in the abdominal cavity

the cavity! Here are three important points I am laparotomies which I have made for gunshot wounds an advocate of the operation, but I have never cut of the abdomen, once seen the intestine escape

A day loose from the traditions of the profession I am a link between the two methods The more I see of I am disposed to hesitate about opening them Every case says to me, "go slow" This case had a good pulse, good temperature, and there were no urgent symptoms But there was a penetrating wound A penetrating wound of the belly is not a warrant for declare that the patient cannot be worsted by the operation, symptoms that make us feel that he will not recover, he has intense pain, vomiting, symp toms that look towards collapse, we should operate But if the man has a good temperature and pulse, and a penetrating wound of the abdomen, with my limited observation, I should hesitate, I should wait I have long been impressed with the belief that the simple fact that the intestine is wounded does not carry with it the absolute certainty of extravasation From actual sight, it is known that many wounds of the intestines heal without extravasation-wounds A wound that is necessarily fatal will be attended with symptoms

Of course no one has greater admira There was a tumor in tion for any view Dr Gregory may express than I However, there seems to be a radical difference of opinion in this case Never, in a case of penetrating wound of the abdomen with the symptoms that Dr Gregory indicated, should a surgeon perform laparotomy, because the patient is going to die any how, he has septic peritonitis I don't believe that on the post-mortem table a gunshot wound of the contrary, I find fæcal matter, inflammation, etc The best possible condition for the recovery from any operation is that the patient is in the best physical condition, pulse and temperature good, before the changes that necessarily result in death have had an opportunity to begin, before fæcal matter has had time to be carried across the peritoneal membrane The time is unquestionably then, when the wound is Again, the mere performance of first inflicted laparotomy after an incised wound does not imply If a man has a more than an explorative incision simple wound of the abdominal parietes, whether it penetrates or not-as I have seen in a case in which there were no symptoms, when the wound was enlarged, a knuckle of the intestine or a piece of omentum was in the wound, the internal end of which was four times as large as the external one The simple enlargement of the wound does not add What were the symptoms gravity to the case, but it does that which is of the utmost importance—it enables the surgeon to ap-His circulation was good, pulse was proximate the peritoneum, to sew up a rent in the If we wait until bowel, or ligature a blood vessel the urgent symptoms appear, there is no use in perwould like to ask Dr Gregory in how many cases of gunshot wounds of the abdomen he has seen the in-And there was no hæmorrhage in testines escape? I have never, in perhaps twenty

I was present at the DR A H MEISENBACH of the wound and the direction of the bullet, and an opinion based on the facts and teachings of experi mental surgery by Senn, Parkes and others in relathose cases in which to perform laparotomy. If the general disturbance of the circulation one of the best subjects for recovery, but as the op that he would ultimately have succumbed speeds, and character of wounds they produce wounds nearest the skin were clean cut wounds Those near the right wing of the ilium were ragged ones, one or two in which peritoneum and muscularis of interest to the discussion, and I think is is a forwere entirely torn away, leaving a valve like opening tunate thing we have a man like Dr Gregory, who in the mucous membrane It seemed impossible stands a little in the breach, because abdominal that with such injuries the patient could recover surgery is a new field, and rules in relation to it are without having those wounds closed up amount of extravasation must have been very little, wounds there seems to be not much room left for the bleeding was very little The danger generally is not from arterial, but from venous hæmorrhage, that occurs from the mesentenc veins

In regard to the technique, the length of time is, the result In this case the patient was on the table from 11 30 PM to almost 3 o'clock in the umbilicus, and he walked home morning, because the search for, and closure of, the ploration with the probe wounds was necessarily very tedious The continuous suture fulfils everything that is demanded of it, and closes the opening so that nothing will exude, can be more rapidly applied then the Lembert or its modifications, and any one can demonstrate this in shot wound of the intestine ever got well an anımal be easily adjusted, it is the ordinary glover's suture Anyone that has tried it knows how tedious the Lembert suture is a difficult operation

Dr Spencer Graves jority of cases, whether there is a wound of the in- cover after gunshot wounds of the bowel testines or not Bull, he removed sixteen inches of the intestines, infliction of the wound, after this, there is a degree and the patient made a perfect recovery

DR H C FAIRBROTHER I have recently seen The urgent symptoms that Dr Gregory two cases of gunshot wound of the abdomen, and has described were not present, jet the history of the symptoms were identical, the wounds were in the the way in which the wound was received, the caliber same place, being one and a half inches below the umbilicus, both cases resulting from shots at short range from revolvers of 32 caliber In both cases the penetration had a downward course tion to the proper course to be pursued in gunshot the pulse was good, there was little, if any collapse wounds, indicated that this was certainly one of There was no great pain, no marked symptoms of lesion had not been so severe this would have been these cases no operation was performed, perfect rest was maintained, the abdominal surface was covered eration demonstrated, the lesions were so severe with warm carbolized applications and recovery en-In the other case an operation was performed, The sued case presented several interesting points, one of three penetrating wounds of the small intestine were which was one that Dr Parkes called attention to, found and united, and the patient died I don't in regard to different missiles moving at different know whether there were penetrating wounds in the The first case or not, but the bullet was of a similar size and force and direction

I have listened with a great deal DR PREWITT The not certain yet. Yet with the experience in gunshot any other procedure It must be remembered that the course of bullets is very eccentric, and many bullets that strike the walls do not penetrate the cavity, and the patients get well, when it is supposed of course, one of the prime factors that influence that they have gunshot wounds of the bowel I saw a little boy who was shot a little to the right of the I made a little ex-He declared that the bullet dropped out and I let him alone and he got Such might have been the case in that of Dr well Fairbrother In the statistics of the late war, Dr Otis has shown that not a single, solitary case of gun-The continuous suture is one that can cases in which it was presumed that the cavity was entered got well, but not where it was certain that Of course if we find fæcal matsuch was the case In a wound of one inch it takes ter, it is irrefragable proof of the perforation from four to six stitches to close it, and with the we have cases where there is a wound of the inteshands smeared with blood, the tying of the suture is times, and yet there is so little evidence, so far as The continuous suture of the shock is concerned and the absence of meteorism, bowel answers every indication, and even in circular that it would be impossible to say that there was a section of the bowel, it can be adjusted in such a wound of the intestine if we would wait for sympway that the bowel can be brought together without toms If Dr Fairbrother could kill his patient and Experiments have shown that it takes a examine that abdomen, and demonstrate that there very short while for the plastic exudation to close up has been a perforation of the intestines, and find the holes from which extravasation may take place that they had healed, it would be one of the grandest It seems to me that there achievements of the day Until that is determined, are certain symptoms that would tell us in the ma- we must accept it as a rule, that patients do not re-The tympanitic resonance, the so absolutely fatal in gunshot wounds of the large incharacter of the pulse and the shock—but this is testine. Where the symptoms that are to be relied not always a result—I think would determine almost upon as positive evidence of perforation of the positively in the majority of cases When there are several wounds of the bowel near together, it is a It doesn't require to open the abdomen to know question whether it would be better to resect the in-testine, or to close the several openings In New wound and determine the fact prior to any lapar-York last year, I saw a case operated on by Dr otomy It must be done within five hours after the

of congestion that indicates septic peritoritis, con the vaginal portion. This patient was 28 years old, sequently, you have to deal with a condition which and in spite of her being a nullipara the operation is most unfavorable So far as inferior animals are concerned, quite a number of cases have recovered where the intestines were injured, but this is not a criterion, because they will stand more than human In regard to the closure of wounds, Dr Parkes has shown that it is better to resect a portion of the intestines than to close a number of wounds The modified Lembert stitch can be done as rapidly as the ordinary whip-stitch, and is quite as effectual

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, Friday, September 24, 1887 THE PRESIDENT, CHARLIS WARRINGTON EARLY, M D, IN THE CHAIR

DR J H ETHERIDGE read a paper entitled VAGINAL HISTERECTOMI, REPORT OF THREE CASES (See The Journal, December 24, 1887)

DR CHRISTIAN FENGER made some remarks on CARCINOMA OF THE CERVIN

The first specimen was from a woman about 40 years of age, a multipara She had had symptoms for over a year, and was in rather an emaciated condition, partly on account of chronic bronchitis and a cystic goitre, and partly on account of the carcinoma, where several local operations had been done It is a cervix carcinoma, with the cervix involved almost to the internal os, the white mass here below being the carcinoma tissue, and all the rest of the cervix being carcinomatous The only thing that induced me to operate in this case was the extreme movability of the uterus As a rule, in carcinomata that have gone as far as this, I do not think operation is advisable, I think it is too late. However, she was not asked by me to be operated upon, but she im plored me to operate on her at any risk to her life, Before the operation her pulse was and I operated 120, and she was, as I stated before, weak, but the that she was very fleshy I think that in a very fleshy uterus was movable and was taken out without any considerable difficulties Before the end of the operation, which lasted about two hours, she was very the nates weak and almost pulseless after the operation during the afternoon, and in the the uterus, which, however, has not given rise to any evening her pulse was 170 and scarcely countable She did not lose any quantity of blood to speak of I made a saline infusion of 12 or 13 ounces into the brachial vein, afterwards the pulse got stronger, and continued so from that time, and there was no further trouble during her recovery

The next specimen is a portio carcinoma extending about an inch into the cervix on the posterior It is a portio carcinoma because it has the greatest extent down at the vaginal portion, and becomes smaller and smaller as it goes up in the cervix If we have a cervix carcinoma that opens down in the vaginal portion, we should expect to have a operation difficult and long, so that at the end of the larger cavity in the cervix and a smaller opening in operation I did not care to lose time in uniting the

was very easy. Inad here, as in all of the cases, to dilate the vagina posteriorly, but otherwise, evidently on account of the small size of the uterus, the operation was easy—so easy that there was no cause for either ante of retroversion while taking it out, it was just held down, and the ligaments ligated case the operation was so easy that I united the pen toneal as well as the vaginal wound, closed them up together with a row of sutures, commencing in the anterior forms, going through the anterior pentoneum, the posterior peritoneum, and out of the posterioi fornix, thus closing up by one row of sutures the peritoneal and the vaginal wound In the other case, I closed the peritoneal wound and left the vagi-The drainage used was iodoform nal wound open She made the most undisturbed recovery of all of them, never had a rise of temperature nor of pulse, and never had any pain The tubes and ovaries were not removed

The third case is a small portio carcinoma, extend ing but slightly up in the cervix, and can be seen on She had previthe posterior surface of the uterus This uterus was perfectly ously had perimetritis movable, but the operation was not easy, as the loosening of the bladder from the uterus was difficult, while in the first two cases it was easily detached with But here, perhaps on account of the pre the finger vious perimetritis, the tissue between the bladder and uterus was so dense that it had to be cut with the scissors, and I made a small opening into the bladder, which was united at the time it was cut, and did not leave any bad results, not even a temporary fis tula, as no urine passed at any time down into the Her recovery, was uninterrupted vagina

The fourth specimen is another portio carcinoma on the posterior lip, reaching up in the cervix per-The patient was a multipara, 28 haps half an inch years old, and quite fleshy Contrary to my expect ations, the operation was extremely difficult vagina was not unusually narrow, but I think the dif ficulty of the operation was due partly to the large size of the uterus, and partly on account of the fact person there is some little part of the vagina nar rowed by the subcutaneous tissue on the inside of There was here the same difficulty as in This condition lasted the previous one about separating the bladder from passage of urine into the vagina I operated accord ing to the method of Leopold, loosening the lower part of the broad ligaments first, and then going up until there are no firm bands left on the sides of the When that is done, and the anterior fornix uterus loosened, as a rule the uterus becomes so movable that it comes down an inch or an inch and a half or two inches into the vulva, so that the rest of the operation is comparatively easy But in this case it There was an unyielding con did not come down dition of the lateral ligaments What the reason was Of course, this condition made the I do not know

cavity open, using for drainage iodoform gauze there packed up in the peritoneal civity This patient did not have an uninterrupted recovery She had a temperature for a couple of days of about 1015°, later on 100° now it is down below 100° pulse was up in the neighborhood of 120 all the time, until now it has finally gone down. In this case I had to change the gauze packing at the beginning of the rise of temperature, taking it out and introducing a dramage tube so as to be able to wash it out every washing out was performed early, the fluid has gone up into the peritoneal cavity and caused general infection

Dr Merriman Do you think that if you had nave saved her much?

Dr Fenger I must confess that I believe in closing the peritoneal wound as a matter of safety The specimens here show one point, namely, that a strict line, as Ruge and Veit have pointed out, between portio carcinomata and cervix carcinomata does not exist. They say that a portio carcinoma very rarely extends up into the cervix. If that is the case it would, of course, not be justifiable, in many cases of simple portio carcinoma, to do anything but the partial operation Fritsch has called attention to a fact which these specimens show very distinctly that is, the difficulty of finding out if a portio carci noma is limited to the portio proper or extends up into the cervix, or even into the cavity of the corpus

I might say a few words in regard to the manner of operating It is very far from being generally agreed upon which operation is the best, and the variety of procedures is very large. As an illustration, we will take the treatment of the broad liga ment and the closing of the vaginal and peritoneal I think there has been an improvement in the technique of operating over the old methods in operating as proposed by Sanger and Fritsch begin the operation by the ligaturing step by step of the parametria When that is done well on both sides, the uterus will become so movable that the remain der of the operation can be done with comparative This ligaturing step by step, together with Martin's method of suturing, does away with one of the dangers of the operation, namely hæmorrhage By this step ligaturing the uterine artery is met half or three quarters of an inch above the fornix, and can be securely ligated, so that the rest of the operation can be done with comparatively little loss of blood The other danger which we have to encounter is sepsis, as we have to do with a carcinoma, whose surface is always decomposed and septic doing the usual and necessary clean operating, Leo pold proposes that we should not antevert or retro

peritoncal or the vaginal wound, but only brought forms closed when we antevert, so that the carcinodown the ligatures to the borders of the vaginal in- matous surface cannot be turned up into the peritocision, uniting them here and leaving the peritoneal neal cavity, and come in contact with the organs

As to the treatment of the peritoneal and vaginal wound, there is also a great variety of methods seems that for after treatment packing with iodoform But what gauze is much more convenient and much less troubalarmed me more than the temperature was that the lesome than a drainage tube, as the iodoform gauze can be left in for a week or more without being removed, and then the after treatment is over

DR NELSON I would like to ask Dr Fenger, in regard to the removal of the ovaries and tubes, whether they are likely to produce disagreeable reday, the washing out, however, not being trusted sults in the after history of the patient by being until after the tenth day, because at least one, per- retained? I can understand full well the desirability haps more cases are on record where, when the of leaving as many organs and as much tissue as can be left, but would raise the question of the desirability or not of removal of the ovaries and tubes when the uterus has been removed

DR FENGER In answer to that question, I would sewed up the cavity of the peritoneum you would say that it is remarkable what little trouble has been reported from the cases where the ovaries and tubes There are a few cases, one of Schreehave been left der's, where the menstrual molimina from the organs left has caused the patient trouble In another case, the ovary or a piece of it which had been left was imbedded in the cicatrix, and caused afterwards, according to the opinion of the operator, periodical Brennecke says that he has come to the con clusion that it does not do any harm to leave the ovaries and tubes in He says that the ovaries atro phy, that some of his patients have had slight molimina in the first three to six to nine months after the operation, and after that time the symptoms from the ovaries have always entirely ceased That is all I know about this question But as we get towards the end of the operation it is hard on the patient and hard on the operator, and I feel like doing as little additional operating as possible, and if I can leave the ovaries and tubes without doing the patient any harm I prefer to do so, as the operation is in many cases a severe one on account of the liabitity of the patient to collapse towards the end of the operation, which lasts for an hour and a half to two hours until I can do the operation much quicker I should prefer to leave the ovaries and tubes in

Dr Merriman Is there any danger of including the ureter in this operation, of injuring it in any way?

Dr Fenger Yes, there is danger, masmuch as it has been done, although very rarely When the ligaturing of the broad ligaments has been done step by step so that the uterus can be drawn down, then the ureter stays up, so that the final ligature of the broad ligaments is not likely to include the ureter

Dr Merriman But in this method that has been spoken of as Martin's, would there not be more danger when the bladder is not loosened?

Dr Fenger Martin ligates step by step, the parametria first, consequently he gets the uterus further down

Dr Merriman He draws the bladder down vert the uterus, but take it out without any of these with it, the uterus and bladder not being disconprocedures Fritsch advises to leave the posterior nected, and I should think there would be great danger of including the ureter in some of the operations

Dr Fenger the bladder when the uterus is made movable and drawn down, the ureters stay up

Dr Nelson Is it customary with the majority of operators to curette and thoroughly disinfect the carcinomatous ulcer before beginning the operation, immediately before, or is it done several days be fore, or is it done at all?

Dr Fenger I think it is done several days before by some, for instance by Hegar and some others Fritsch and Leopold do it at the beginning of the After the curetting, the surface is disin fected by a strong solution of chloride of zinc or a strong carbolic acid solution I prefer to postpone it to the beginning of the operation so as not to have the patient disturbed with an additional opera tion, with some loss of blood

DR MERRIMAN Supposing there was a case of cancer that had gone beyond the cervix into the tissue posterior to the uterus, invading the vagina and extending along down on the arterial side, but there was nothing anterior to the uterus, would it be safe in a case of that kind to undertake the operation of extirpation?

Dr Fenger I think I should refuse the benefit to the patient lies in operating early, and as soon as a portio carcinoma has gone over on to the wall of the vagina to any extent, I think the prospects of a radical cure are very small, and that the patient is just as well off with symptomatic treatment, curetting, etc I think the aim of the opera tion should be a radical cure, and that extensive operating is being done away with more and more, and only limited cases regarded fit for operation

Has the vaginal hysterectomy become less danger ous since its revival by Czerny in 1879? The mor tality from the operation for the first five years up to 1884 has been given by Mundé to be 28 per cent In a paper read before the Amer Gynecological Association in 1884, he tabulated all the cases to be found in the literature from Europe as well as the United States, the operations amounted to 255 with 72 deaths = 28 per cent For the operations of the year of 1885, recorded in Virchow Hirsch's Jahres ber icht, 1886, the mortality is already considerably I find reports from 32 operators In all 106 cases with 17 deaths, or 16 per cent A Martin reports, in his work of 1887, 66 cases with 11 deaths = 166 per cent Special reports from individual operators in the last year show even more favorable results

Thus we find reported by Klotz, 17 cases, no deaths, Gaillard Thomas, 15 cases, no deaths

Most valuable, however, are, on account of the larger number of cases, the recent reports from Fritsch and Leopold Fritsch reports 60 cases with 7 deaths, 10 1 per cent, Leopold reports 48 cases with 3 deaths, 6 2 per cent mortality

The reports of both last named operators include all of their operations from 1883 to 1887 Leopold's mortality of 6 per cent is the lowest yet recorded for a larger number of cases Every operator has, undoubtedly, in the beginning of his work in this seem to be much smaller than that of the total extirpation

line, operated on cases that were too far advanced Even if the ureter is caught with for a reasonable hope of permanent eradication of The more recent the origin of the the disease tumor, and consequently the more limited the extent of the growth, the better are the prospects, as well the immediate as the remote, for the patient then, in future, the cases for operation are properly selected, we can expect that the mortality will reach a reasonably low figure, and I think we must agree with Fritsch in the following statements (p 385,1 c) "I have no doubt that in a near future the mortality in general will come down to 3 or 4 per cent "

It certainly seems remarkable, and far surpassing the expectations with which this operation, less than ten years ago, was reintroduced in surgery, that in so short a time its mortality should come down to almost the same point as in laparotomy for ovarian Ovariotomy needed a much longer series of years to reach the point of safety it possesses Vaginal hysterectomy for carcinoma can be said now to be not more dangerous than the extirpa tion of a carcinomatous mamma with removal of the axillary glands, for which operation Billroth' gives a mortality of 105 per cent Schmid, from Kuster's Hospital (Auguste Hospital, Berlin), 5 2 per cent

Are the partial operations on the carcinomatous uterus, provided they permit of effective removal of the tumor, preferable as being much less dangerous than the total extirpation?

Pawlick reports a large series of partial galvano caustic operations from Brown's Klinik in Vienna

137 cases had 10 deaths = 7 2 per cent, from 1m mediate effects of the operations

In 12 of the cases of recovery, late hæmorrhages of a severe character were observed

Schroder reports 105 vaginal amputations of vag inal portion and cervix with 13 deaths from sepeis = 12 3 per cent Wallace reports 10 cases with 2 Gusseron has 33 cases with deaths = 20 per cent

3 deaths = 9 per centWe can thus conclude that, if the mortality of total hysterectomy is in the neighborhood of 10 per cent, the operation is not much more dangerous than the partial vaginal operations 6 A much larger field than hitherto will undoubtedly be accorded to It is, in many cases, almost impos the operation sible to determine how far up into the walls of the uterus the carcinoma tissue extends mortality of 25 per cent for the total extirpation, Gusserow, in doubtful cases, will prefer this opera tion to the partial operations, and he states in this "The safer total extirpation connection as follows becomes, the more it will take the place of the vag inal amputation of the cervix "

A much cited case of Binswanger is of importance in our choice of operation He found a perfectly isolated portio carcinoma, accompanied by an also isolated carcinomatous degeneration of the mucous

Deutsche Chi 1 Bilroth, Krankheiten der Brustdrüsen, p. 155

how localized a small carcinomatous nodule may be, axilla, would be the safe operative procedure to his patient operation to be done in all cases of limited carcinomas, even small carcinomas of the vaginal por tion, to the exclusion of any of the partial operations

Fritsch calls attention to the fact that a strict demarcation line between carcinoma of the cervix and of the vaginal portion, as Ruge and Veit in their classical article on uterine carcinomas have described it, does not exist in all cases Some apparent portio carcinomas extend deeply up into the cervix It is often not possible during a partial op eration, viz, vaginal amputation of the cervix, to de termine if we amputate in healthy tissue

Consequently, for the majority of such cases the total extirpation is safer as to radical cure of the

carcinoma than a partial operation

DR H T BYFORD I had the good fortune to successfully operate upon one case in which the uterus looked something like this larger one Professor Fenger has shown us It was probably an inch The patient was a fleshy married lady, about 30 years old The cervix had been amoutated a few months before I ligated the broad ligaments step by step, as recommended by Leopold I left ligatured parts together, and then packed the vagina with iodoform gauze for eight days By mistake one of the iodoform tampons was left in nearly two weeks, but it did not cause any serious symptoms As to leaving the peritoneal cavity open, I think there never will be a cast-iron rule, for that will probably have to be decided by the case If the case was one in which there was much manipulation of the broad ligaments we would expect some sero sanguinous exudation, and should not completely close the peritoneal cavity When we use iodoform gauze in the proper shape we practically close it up I do not see the use of sutures Before there can be any decomposition of secretions, the peritoneal cavity is closed by exudation Stitches, are only a source of irritation, both during and after the place As to leaving the ovaries, it seems to me that in taking out the uterus we take out the larger portion of the sexual nervous system and produce atrophy of the sexual organs quicker by removing the uterus than by removing the ovaries be almost as superfluous to remove the ovaries after the writer has met with taking out the uterus as to remove the uterus after) taking out the ovaries to bring on the menopause and thus rapidly finish the operation In regard to cles, and others are found free in the blood

membrane of the fundus It is generally accepted that taking out the uterus is not so very much more as a law in the surgery of the mammary gland, that serious, although much more difficult, than amputating the cervix It cannot be so safely done so nothing less than the removal of the entire gland, often by the inexperienced operator, for he is more and I regard it safe to add the lymphatics of the liable to do something that will endanger the life of But when the operation is properly adopt It can thus be understood that authors who performed, the peritoneal cavity practically closed believe in a low mortality for the vaginal hys-by the parts being brought together, the patient is terectomy—Sanger, Leopold, Fritsch—require this left in as good condition for recovery as by a high amputation combined with the cautery

DR J C HOAG I have observed with a good deal of interest an apparent revulsion in feeling and opinion with regard to the advisability of this operation Only a few months ago, in conversation with a number of operators in England I found the operation was very generally decried, but since that time, from a perusal of the English journals, one gets a different idea of the opinion of the British operators Some of them did not hesitate to say that in those cases which recovered there was no carcinoma regard to the technique of the operation, I can only speak in the light of what experience I have had in practice on the cadaver, under the instruction of a prominent operator I was instructed to begin the operation by opening the anterior and posterior culde sac This certainly seems to be an inferior method to the one one described by Dr Fenger, as affording opportunity for infection of the peritoneum one advantage, however, and that is, it enables one to get his bearings better in regard to the relation of the parts, because one can surround the broad ligaments with the finger and find just where to pass the the abdominal cavity open except to draw the ligatures, and in this way I think the ligatures can be put in in a more accurate manner The loss of blood is less, and after the removal of the uterus there is no trouble whatever from hæmorrhage because it is entirely prevented by the acucrately applied ligatures, whereas in the other methods there is often a considerable loss of blood In a number of cases which I saw the operation was practically bloodless

(To be concluded)

PATHOLOGICAL SOCIETY OF PHILADELPHIA

Semi-Annual Conversational Meeting

THE PRESIDENT, F P HENRY, M D, IN THE CHAIR

DR W T COUNCILMAN, of Baltimore, delivered an address on

SOME FURTHER INVESTIGATIONS ON THE MALARIAL GERM OF LAVARAN

This organism, first described by Lavaran, has It would been met with in every case of malarial fever which The organism is in high degree polymorphous, and ten tolerably distinct forms may be found in the blood Some of these There is one kind of operation which has not been evidently represent different stages of development, referred to, that is by leaving compression forceps and the connection between them is obvious Others on the stumps, as is done quite extensively in France present such marked differences in form that no con-When the patient is very weak it nection between them can be made out Some of seems to me an improvement to put on these clamps | the forms are only found outside of the red corpus the mortality and difficulty of the operation, I think are 1 Non pigmented small amœba like bodies in-

side the red corpuscles, 2 pigmented bodies larger than No 1, also in red corpuscles, 3 pigmented bo dies about the size of red corpuscles, 4 segmenting forms of the No 3 body, 5 small hyaline bodies, which are formed by this segmentation, 6 a cres cent-shaped body with pigment in the centre, the horns of the crescent being often connected by a fine line, 7 round or oval bodies which differ from No 6 in shape only, 8 a pigmented body provided with numerous long, actively moving flagellae, 9 actively moving free flagellæ, which are evidently derived from No 8, 10 a pigmented body with an active undulatory movement of its periphery. The first five forms are found only in intermittent fever, No 4 only being seen in the blood during the chill pe riod, and its presence is invariably connected with the chill, Nos 6 and 7 are found in cases of malarial cachevia

The most interesting forms, and about whose parasitic nature there can be no doubt, are the bodies Nos 8 and o These are generally absent in blood taken from the finger, but they may be found in any type of the disease They are the only forms of the organism whose presence in the blood is not asso ciated with a special type of the disease. They were found, however, in fifteen out of the twenty cases in which the blood of the spleen was examined these twenty cases twelve were cases of malarial cachexia, and eight of intermittent fever twelve they were found ten times and in the eight cases of intermittent five times From this it seems probable that Lavaran was right in considering the flagellate organism the most important form of the The influence of quinine on the intracorpuscular forms of the parasite is most marked Doses of 15 grs t 1 d for two days in succession were found sufficient to cause them to disappear The effects of the quinine were not so apparent in the other forms The crescents were apparently not diminished in number in one individual after he had taken 45 grs of quinine daily for seven days, and 60 grs daily for four days

DR WM OSLER said the thought which had struck him most forcibly, in looking over this subject, was the almost perfect unanimity which has prevailed among the different observers as to the appearance of these organisms With the sole exception of the segmented form (No 4), Lavaran and the early observers had described them all His own observavations, since the communication he had presented to the Society last year, had been somewhat limited He had, however, made a series of observations upon the blood of fishes and birds, since it had been stated that bodies resembling Nos 1, 2 and 3 had been found in the blood of carp and some water-fowl Prof Baird had offered him facilities for this work at Wood's Hall, and had kindly furnished him with forty five carp He had failed to detect any such organisms in the blood of these In the blood of a goose sent him from Ontario he had found one or It had been been stated by two pigmented bodies Dr McCallum, who sent him the goose, that the eventually disappear? However, the bodies were not bird had malaria numerous, nor was the temperature of the goose ele- as described by Hutter some twenty years ago?

vated, nor, so far as he could make out, had it chills Dr Councilman had not figured one body that is very peculiar indeed, namely, a solid body in the centre of a clear space. It stains like a microorganism, varies in size, and although the body itself does not change in form, yet there are sometimes changes in outline in the clear space surrounding it They were somewhat abundant in one case only

One other point with regard to the clear bodies (No 1)In five or six instances he had seen such bodies pass out from the corpuscle, remaining out and undergoing no further change of form He was not altogether prepared to say what was the rela tionship of these bodies to the other bodies de-It has been claimed that similar changes can be obtained by special methods of treating the The most important question is first to de termine the relationship of the hyaline to the pig mented bodies, and the possibility that the hyaline He was may not be directly associated with them convinced that the pigmented and segmented bodies were merely different stages He could fully con firm what Dr Councilman said with regard to the They are most peculiar and interesting crescents bodies, occurring in the chronic cases and in those in which there had been no chills Three weeks ago he had diagnosticated a case as one of mild typhoid fever, it had lasted eight or ten days, with constant fever, up in the evening, down in the morning, slight enlargement of the spleen, no spots His Res ident examined the blood and found what he thought The case got rapidly better, left the were crescents hospital, and returned in a few days with a distinct chill, with crescents in the blood and a well marked The mobile forms he had not seen remittent fever nearly as frequently as Dr Councilman, though he had not examined the blood from the spleen they had been present in eight or ten cases Nor had he seen free filaments nearly so often, when he wrote his paper he had not seen them at all Since then he had watched the process of separation out of the question to suppose that the crescents or mobile forms could come from degeneration in the stroma of the corpuscle, but that the hyaline forms resulted from such changes was not altogether improbable, and further investigations were necessary to determine this point

DR J P C GRIFFITHS called attention to the di agnostic value of these organisms, and instanced a case where from the indefinite history and symptoms he was unable to make a diagnosis until after an examination of the blood, when a short course of treatment resulted in a cure

DR H C Wood said that no one seemed to have made any connection between the crescents and the amœboid forms, they seem to differ in that these are destroyed by quinine, those are not affected We know that malarial cachexia is cured by quinine, arsenic and iron If these remedies have no effect on the crescents, what connection have these bodies with malaria? and what becomes of them, do they

DR FORMAD asked if these organisms are the same

DR COUNCILMAN said, in conclusion, that Hutter described moving bodies attacking the red corpus cles, existing in all fevers and apparently almost everywhere else These observations had never been confirmed The point rused by Dr Wood had always puzzled him, and for a long time he had tried to reconcile himself to a belief in two distinct dise ises, but this he could not do, as always as the other forms disappear the crescents appear had never seen the crescents unless with a history of previous chills He was not altogether prepared to say that quinine had no effect on the crescents, though in several cases he had given it in large doses with no results Still in some cases they do seem He thought with Dr Osler that the to disappear crescents could not be possibly produced by changes in the stroma of the corpuscles though some of the other forms might

Hydrofluoric Acid in Phthisis-Cause and Preven tion of London Fogs-Cow pox in England-Preven tion of Pollution of Rivers by Soap and Other Works -Multiple Sarcoma with Osteitis Deformans

Hydrofluoric acid is spoken hopefully of as a new treatment for the cure of phthisis The patient passes one hour out of the twenty four in a room of the capacity of six cubic metres, into which a current of air is pumped which first passes through a fluid composed of 100 grams of hydrochloric acid and 300 grams of distilled water The proportion of hydrofluoric acid taken up in the cold under such circumstances would vary greatly with the bulk pressure for water alters the cough immediately, quickly diminishing it, and occasioning its complete cessation in a few days, the bacilla of the sputa concurrently disappearing Fifteen or twenty days suffice to greatly benefit the patient, if not to cure him entirely Out of nearly a thirty five were cured, forty one greatly improved, fourteen seemed unaffected either way, and ten deaths took place The action of the acid is consid ered a purely antiseptic one, and several well known

Sir Donglas Galton recently read a paper at the Parke's Museum Hygiene upon the cause and pre vention of those dense fogs which appear yearly to Europe and America become more frequent and severe in London

contained four times as much carbonic acid as ordin ary London an, and that might be taken as an index of the quantity of other impurities which a fog accumulated Fog was caused by the floating matter in the air attracting to itself the aqueous vapor which was always more or less present Some forms of matter, such as ammonia and sulphur, had a gierter affinity for vapor than other matters substances were present in London air to a great The blackness of the fog. and unnecessary extent came from the smoke arising from incompletely If smoke was to be avoided housesburned coal must be warmed by hot air, hot water, steam or gas, as in the so called smoke preventing open fires care was required in putting on coals and nobody exercised that care

A report of the Agricultural Department of the Privy Council is a curious example of the unexpected result to which scientific inquiries sometimes lead-The result of an inquiry by Dr Klein, FRS, made for the Local Government Board and published last February, appeared to establish the fact that milch cows could suffer from scarlet fever, as Dr Klein and Mr W H Power in the inquiry as to the cause of an outbreak of scarlet fever in Marylebone, traced the milk supplied from a certain dairy farm and ascertained that the cows were suffering from a contagiouseruptive disease The same microbe was found in the discharges from this cow disease as was found in the blood of persons suffering from scarlet feverconsequently the conclusion was arrived at that the human being caught the scarlet fever by drinking the milk of cows thus diseased This theory was adopted by the Local Government Board The Agricultural Department took the matter up and instructed Professor Crookshank of the Bacteriological Laboratory of King's College, to make an independent inquiry. Professor Crookshank has arrived at the conclusion that this cow disease has nothing to do with scarlet and velocity of the air current, but would in no case fever, and that the milk which gave the disease must be large, owing to the great attraction of this acid have been contaminated in some other way, probably It is, however, stated that this treatment through the hands of milkers But this new inquiry has done something more than prove the previous investigation to be wrong, it has most unexpectedly turned up a new fact of great practical importance It is not necessary to follow the Professor through all the somewhat intricate steps of his argument, suffice hundred cases in various stages of the disease treated it to say that he has apparently proved beyond the during some ten weeks this autumn it is alleged that range of reasonable doubt that this eruptive disease of the udder of the cow is true Jennerian cow pox It is a curious fact that for the last thirty or forty years this disease has not been heard of in England, although at the time when Dr Edward Jenner pubphysicians are about to make systematic trials of the lished his great discovery, just ninety years ago, it was commonly seen in the dairy farms of the West of England During the same period there have been but two or three cases observed on the Continents of When it was determined to The establish vaccination from the calf at the National lecturer said that black fog was entirely the result of Vaccine Establishment, the first supply of lymph smoke, one rose to see a lovely sky, but an hour to vaccinate the first calf had to be obtained from later, when fires were lighted the brightness was the Hague and Bordeaux, but since then the civilized dimmed and the sky and light disappeared Dr world had to depend for its vaccine upon stocks de-Russell's experiments showed that the air in a fog rived from one of these sources, or from the human

that cow pox, or vaccinia, has again occurred spontaneously in this country The dairy farmers and the Agricultural Department are not only triumphant but have returned good for evil Accused of dissemminating scarlet fever, they present the world with a new source of vaccine lymph supply

At Rochdale an invention to prevent the refuse of soap and other works polluting rivers has been successfully tried The water containing the dissolved lifying soap is run into a large vault, over this vault are two elevated tanks of the same size and beneath them a retort is fixed. The soapy water is pumped from the vault into the elevated tank and chlorine, generated in the retort from hydrochloric acid and maganese, is forced into the liquid This causes the refuse and fatty matter to gather in a cake at the bottom water in the tanks is run off into the river containing performed without the final closure of the inguinal no foreign matter with the exception of a little com-The cake of fatty matter and dirt is then mon salt treated, the oil extracted by pressure and filtration is ating Dr Burchard said that his experience had led made into brown soap exactly like that which is used him to the adoption of a plan of treatment substan in the process of washing raw silk. The inventor tially as follows has been offered £20 per ton by wholesale dealers for the reclaimed soap

Dr G F Elliott, at the recent meeting of the of morphia and atropia Medical Society, contributed the notes of a case of multiple sarcoma, associated with osteitis deformans, There was no history of syphilis, in a man, æt 27 and until February, 1886, the general health had Pain, attributed to rheumatism, then been good appeared in the knees and shoulders In December, 1886, the hands and feet were noticed to be enlarged In June his upper extremities from the fingers half way up the humerus and his legs from the toes to and including the knees were found to be ædematous There was marked thickening of the bones clavicle and some ribs on the right side were also thickened The skin of the face and hands presented numerous small flattened nodules about 1/8 in in diameter, there was more or less hyperæthesia of the first been obtained to proceed with the operation in skin of the trunk There was pleural effusion over the left lung Later on troublesome diarrhœa super-Nine days before death the patient insisted on going home and was thus lost sight of The diagnosis was premised from cancerous growth on the thoracic duct and Dr Hilton Fagge's authority was quoted in favor of the nodules being indicative of a sarcomatous growth

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

A Symposium on Hernia—Treatment of Strangulated Herma, Management before Operation, Principles of the Operation-Conservative Treatment of Irreducible Hernia—Strangulated Hernia in Children —Telegraphic Mind-Cure

At the December meeting of the Academy there was a "symposium" on the subject of hernia was led off by Dr T Herring Burchard, who gave lation, so that surgical relief could now generally be

It is, therefore, extremely interesting to find a clear exposition of the modern treatment in stran gulated hernia, and strongly urged the advantages of early operative interference He said that, encouraged by the remarkable success obtained in the treatment of strangulated hernia by the methods suggested by Mitchell Banks, Czerny and others, surgeons had latterly paid special attention to the radical cure operation as applied to cases in which strangulation existed, and the results achieved had been most grat The modern operation found its greatest advantage in the radical cure it secured by the com plete closure of the sac and the permanent oblitera tion of the canal, and it had been successfully per formed upon all forms of hernia, inguinal, femoral and umbilical, with equally satisfactory results. In the light of these facts he thought that no operation for strangulated hernia could be said to be properly canal

With regard to the management previous to oper

r Pain is allayed, vomiting quieted, and nervous tranquility secured by the hypodermic administration

2 As soon as practicable a careful examination is made of the hernial tumor, any attempt at reduction being studiously avoided

3 If evidences of inflammation are found, or if there is much swelling in the tumor, a poultice of flaxseed meal and cracked ice, or the ice coil, is at once applied, these being dispensed with, however, if the patient is feeble or the strangulation is of long standing

4 A stimulating enema of turpentine and oil, or a large emollient one of flaxseed tea, is administered, and the rectum thoroughly washed out If the tumor is at all distended no attempt at taxis is made until,

The patient is anæsthetized, permission having case taxis should fail

He especially emphasized the advantages to be gained by putting the patient under full anæsthesia (preferably by chloroform), covering the tumor with a rather large and heavy ice poultice, elevating the lower extremities, and keeping the hands entirely off for a period of from thirty to forty minutes In a number of instances, he said, he had had the satis faction of seeing the tumor slip back of itself, almost imperceptibly, even after prolonged taxis had been unsuccessfully employed As to just how long the attempt at reduction was justifiable, no absolute rule In some cases it was advisable could be laid down that the trial should be kept up for twenty, or even thirty minutes, provided always that only the most gentle manipulations should be employed

Taxis having proved unsuccessful, the operation should at once be undertaken, and the general prin ciples upon which, as a legitimate surgical procedure, it was based, were the following

r A more general recognition by the profession of the value of time in the earlier stages of strangil

remediable had taken place in the tissues

tices which, founded in a false pathology, sought to used as a causative agent in the production of strangulation, never exists

3 Modern hermotomy restricts the employment of taxis to within limits which are rational and safe Necessary as properly directed taxis is in the reduction, by its indiscriminate and reckless use irreparable damage has not infrequently been done the intestine

4 Modern hermotomy implies the early resort to a cutting operation Many lives, Dr Burchard said, extravasation and stercoraceous vomiting, the perifactors of the primary condition of strangulation, but secondary complications, developing later on in the progress of the disease, and the legitimate result of delay in affording relief to the original constriction reference to strangulated hernia in children

of the hernial sac the finest impartiality of judgment Certain cases require incision, while in others the strangulation can be readily reduced without opening the sac, so that it would be folly to thus complicate the operation and expose the patient to unnecessary danger

7 Since Mitchell Banks, of Liverpool, has urged the possibility and expediency of perfecting the old operation of kelotomy, so as to add to the operation done for the relief of strangulation the inestimable advantages of an operation for radical cure, the strongest possible encouragement has been given for the attainment of an early, thorough, and perfect operation

Dr V P Gibney said that he should like to make some protest against the strong condemnation of taxis which Dr Burchard had expressed, as he had seen a reduced under taxis as employed by the average

practitioner

Dr Robert F Weir remarked that while the radical operation unquestionably marked an improvement in this field of surgery, it could not as yet be regarded as a perfected operation, and having given some statistics showing the comparative frequency practicing the operation, and he feared too freelythat is, too freely in non strangulated hernia

Dr W B De Garmo read a paper on the connot treat of strangulated herma, but advised a course in children of gentle manipulations in cases which were gener- his experience, and he had never found it necessary ally regarded as irreducible The first thing to do, he said, was to get the mass freely movable in the sac, and then use compression, rather than ordinary and students of medicine might as well at once begin

rendered before pathological changes which were ir separated from the vicinity of the testicle, if it was situated in the rectum In other words, it was to be 2 Modern hermotomy implies an abandonment perseveringly stripped from its lower adhesions, and of those uncertain and pernicious methods and prac-|gradually worked upwards, no force whatever being The complete separation of the omentum so relieve the strangulation by producing a condition of frequently forming a part of the mass was accomsystemic relaxation It is now recognized that spasm, plished before the reduction proper was commenced By taxis he explained that he meant the gentle manipulation of the neck of the sac, but employed in such a way as to avoid pressure back against the abdominal rings, which was apt to be resorted to in taxis as commonly practiced The manipulations were to be kept up for from fifteen to forty five minutes at a time and repeated once a day cases he was in the habit of directing self applied After the reduction the hernial sac usually had to be sacrificed before the profession seemed to remained, but if the hernia was kept properly in realize that the gangrene and ulceration, the fæcal place by a well fitting truss, the sac often disappeared m the course of time Out of ten cases reported tonitis and collapse, were not necessary and integral by Dr De Garmo, there were seven reductions and two failures, while one case was abandoned on account of the patient's having diabetes

An interesting part of the discussion was that in Modern herniotomy is an antiseptic operation, G Gerster read a paper on this subject in which he demanding the fullest application of Listerian prin- reported four cases operated upon, and said that there was one point of difference in the treatment 6 Modern hermotomy requires in the disposition required as compared with that in adults, this being due to the difficulty of preventing infection of the external wound in small children Primary union did not occur after suturing, and he therefore advocated an open treatment of the wound It was his practice to pack it with iodoform gauze in order to

secure an aseptic condition

Dr Weir said that he had had two cases in children, like those of Dr Gerster, in which he operated, and both had proved fatal In two other cases he had successfully reduced the hernia without operation, by resorting to the expedient of inserting the finger into the rectum, and thus combining internal

with external pressure

Dr Gibney, who has had an unusually large experience in the matter at the Hospital for Ruptured and Crippled, said that he did not recall a single instance of strangulated herma occurring in childhood in which number of aggravated cases of strangulated hernia it was not possible to reduce the strangulation with the aid of chloroform Furthermore, he believed that if the herma could be reduced in children, it could be cured simply by the wearing of a suitable As, in addition, the operation was a more serious one than in adults, he thought, therefore, that operative interference should never be resorted to in children, and such interference became all the more of relapses, he said that surgeons were everywhere unnecessary in the light of the successful results accomplished by the conservative methods advocated by Dr De Garmo

In concluding the discussion Dr De Garmo said servative treatment of irreducible hernia, which did that he had met with only temporary incarceration No serious results had ever occurred in

even to resort to taxis in such cases

Dark days are in store for the medical profession, In the second place, the tumor was to be to devote their energies to some other calling, if the

wonderful reports lately published in the newspapers trustees of the New York State Custodial Asylum are to be accepted with entire confidence anybody becomes ill now it is only necessary for the friends of the patient to telegraph to "Dr" Dresser, "the great mind healer" of Boston, and prompt recovery will immediately result. At all events, this is what the newspapers tell us occurred the other day, in the case of a little girl 11 years old, in Brooklyn, who was "seriously ill with remittent fever" "Three eminent physicians" assured the parents that there was nothing to be done for the child except to see that she had good nursing In spite of this advice, however, she continued to grow worse, until she was "actually at the point of death" In this emergency a telegraphic message was sent to "Dr" Dresser, in For an hour she remained unconscious, during which time, we are informed, the great mind healer was "working on her," and "in half an hour she was as well as ever "

A CORRECTION

Str —I observe in an article on "Conservative Gynecology," Dr Horatio R Bigelow says that he cannot agree with the view tendered by one surgeon "When in doubt, open the abdomen and find out" He thinks a more accurate diagnosis should be made in every case before advising abdominal section This is not the first occasion by many times on which I have had to correct this deliberate misquotation by Dr Horatio R Bigelow He does not indicate me this time by name as he has in other instances, but the quotation which he says he takes he specifies in other instances to be from me

I have never said, and I do not believe any other living surgeon has ever said, "when in doubt, open the abdomen and find out" What I have said is "The abdomen should be opened in cases of doubt only when there is risk to the life of the patient or when the patient is in a serious condition," a very different thing indeed from Dr Bigelow's words LAWSON TAIT am, etc,

QUADRENNIAL DISCOVERY PRIZE OF £1000 —1887-1800 — In accordance with the terms of the Grocers' Company's Scheme, the Court announce that the problem proposed as the matter of

competition for the first Discovery Prize, (1883-1886) viz
"Fo discover a method by which the Vaccine Contagium may be cultivated apart from the animal body, in some medium or media not otherwise zymotic —the method to be such that the Contagium may by means of it be multiplied to an indefinite ex tent in successive generations, and that the product after any number of such generations shall (so far as can within the time be tested) prove itself of identical potency with standard vaccine lymph," has not been solved by any of the candidates. The Prize has, therefore, been withheld, and the same problem is, subject to the conditions of the Scheme, again proposed for investigation. The Prize is open to universal competition, British and foreign Competitors for the Prize must submit their respective treaties on or before December 31, 1890, and the award will be made as soon afterwards as the circumstances of the competition shall permit, not later than the month of May, 1891 In relation to the Discovery Prize, as in relation to other parts of the Com pany's Scheme in aid of sanitary science, the court acts with the advice of scientific assessors All communications on the subject are to be addressed to the Clerk of the Grocers' Company, Grocers' Hall, London, E C

THE GERMICIDAL, ANTIZYMOTIC, ANTISEPTIC, AN-TIPYRETIC, DISINFECTANT, AND OTHER MED-ICAL PROPERTIES AND APPLICATIONS OF NITROHYDROCHLORIC ACID

> BY GEO J ZEIGLER, MD, LATE PHYSICIAN TO THE PHILADELIHIA HOSPITAL

In the eager search for new remedies, and especially in the present earnest quest for more efficient germicides and antipyretics, we are apt to overlook the known merits or undiscovered properties of the old ones, whereas, while we welcome the new, we should cherish the old and good, and seek the additional advantages which a closer scrutiny of them af-Of none is this more true than the agent under consideration—nitrohydrochloric acid, which, as its name indicates, is a compound of nitric and hydrochloric acids in different proportions, by their combination forming the well known nitrohydrochloric acid, or aqua regia a series of remarkably valuable medicinal and other tonic, and healing properties qualities rendering it applicable for a wide range of sanative and remedial purposes, as well as useful in the arts Thus, as it yields free chlorine in a nascent and most active state, appreciable by the taste and smell, in an acceptable, easily tolerated and agreeable form, it constitutes at least one of the most powerful, safe, and useful germicides, antizymotics, septic, disinfectant, oxidizer, chemico organic alteraaltogether it is antalkaline, germicidal, refrigerant, febrifuge or antipyretic, antiseptic, antizymotic, antitoxic, antiperiodic, antiscorbutic, antihæmorrhagic, antiphlogistic, antipyic, antilithic, alterative, disin fectant, sialogogue, cholagogue, lavative, diuretic, secernent, depurant, resolvent, digestive, stimulant, vivifying, restorative and tonic, its acidulous, oxidiz ing, purifying, refreshing, digestive, invigorating, vitalizing, and other salutary properties rendering it very acceptable to the stomach and animal economy, thus forming a rich and peculiar combination of sanative and medicinal qualities, independent of its extraneous adaptation in the arts

drochloric acid is generally applicable in all pathological states of superalkalinity of blood and system, local and constitutional, benign and malignant, such as scorbutic, purpuric, hæmorrhagic, inflammatory, suppurative, gangrenous, ulcerative, purulent, sanious, dropsical, and analogous disorders, especially of a toxemic, lithemic, uramic, bilious, albuminuric, serous and mucous character, and of a more malignant type, as pernicious fevers and conditions generally It is particularly efficacious in all superalkaline, scorbutic, zymotic, septic, contagious, malarial, toxæmic, cholemic, and uræmic diseases, adynamic fevers, and infectious affections, with those maladies dependent upon a necræmic, mephitic and putrescent condition, even with local lesions both internally and externally, though rather too active and laxative in general for those in the gastro intestinal canal connected with typhoid or enteric fever, cholera, and like abnormalities, for which the milder and more astringent hydrochloric, sulphuric, phosphoric, hydrobromic, and other less exciting acids are usually preferable, separately or with their compounds of iron and lime more This agent is endowed with especially, which increase their constringing, styptic,

Asepsis should be general as well as special, from the interior as well as exterior of the animate body, and include the entire organism, or universal in its range and application, as the primal cause of the development of microscopic plants or pathogenic germs, concomitant toxic matter and disease both benign and malignant, is general The basic material or antiseptics, and disinfectants known Moreover, it pabulum vita for the germination, sustenance and probably supplies nascent oxygen from the reaction growth of these parasitic vegetal organisms, microof its constituents, another potent antizymotic, anti-zymes or germs, and the production of poisonous or infectious matter in the vital economy is the same as tive, purifier, resolvent, nutrient and vitalizer, while for plants of all kinds, with their products, outside of the living body, in the earth, air and elsewhere, viz the volatile organic alkali ammonia, for every variety and form of plant, microscopic or macroscopic, within or outside of the vital organism, derives its nourishment and support therefrom therefore, there is a sufficiency of this ammoniacal pabulum for the sustenance of vegetal organisms, they will germinate, grow and develop after their kind, bear fruit, food, poisons and other matters, good, bad or indifferent, inside as well as out of the living animal body, this being, in fact, a constant spontaneous generator of ammonia and its compounds, carbonate, urea, etc, with its adjuncts car-With few exceptions, mainly from local lesions in bonic acid and water, the essentials of vegetal develin the gastro-intestinal canal and kidneys, nitrohy-opment and growth everywhere, of every form, kind pal and most important, and hence the basis of the poisonous and mephitic matter in the mouth, throat, science and art of agriculture in all its departments, microscopic as well as macroscopic There is thus a constant generation of this ammoniacal principle and plant food in the animal economy, which from various causes often passes the normal and becomes superabundant and directly a source of excessive fluidity of blood and disease of various kinds, as well as pabulum for the support, growth and evolution of these cretion, excretion, or defecation, and life action genparasitic microphytes, toxic ptomaines, poisonous alkaloids and other foreign and morbific matters in Therefore, if you neutralize, dethe living body compose, eliminate or destroy this superabundant ammoniacal material and vegetal food upon which all microscopic as well as macroscopic plants thrive, you prevent the development of or starve these bacteria, microphytic poisons, and other extraneous entities in the vital organism, the same as sterilizing the soil will prevent the evolution of or starve all kinds of plants and products in the earth This can be more or less readily effected by an antalkaline and acidulous regimen and medication, one of, if not the most powerful counteracting and destructive agents for the purpose being nitrohydrochloric acid antalkaline, germicide, antizymotic, antiseptic, antipyretic and disinfectant this is exceedingly active, whether the superalkalinity, germs, or toxic matters are of a primary or secondary origin, pathogenic factors or results of morbid conditions, here is an agent that meets all the requirements, safe, salutary, agree able and acceptable to the human stomach and system, or entire animal organism, and of general application, that will prevent and destroy them time largely, and correct the consequent disorder they occasion, or underlying superalkaline, ammoniacal, and other abnormities upon which they are depend ent, as well as remove the fevers or other morbid states resulting from and connected therewith Though the practical fact that this acid medicament, with the acid regimen and medication generally, resolves and cures these so called germ diseases, is worth more than volumes of hypothetical speculation respecting their origin, yet it is necessary for scientific precision and therapeutic perfection to determine the causative factors of disease positively, speculation being as essential to the advancement of is a specific for all forms of asthenic inflammatory, medical as all other branches of science

In ship, typhus, bilious, remittent or malarial, scarlet, puerperal, and other fevers of a malignant and adynamic type, with variola, rubeola, quinsy or putrid sore throat, diphtheria, erysipelas, carbuncle, and other zymotic, septic, pyæmic, contagious, and pu trescent diseases, as well as in the minor scorbutic, necræmic, diphtheroidal, carbunculoid, gangrenous, and inflammatory affections, I have given nitrohydrochloric acid freely, and with so much success that I now habitually prescribe and rely upon it therein as the basic and specific remedy for the underlying constitutional dyscrasia and superalkalinity of blood, as well as general resolvent of their sequelæ, though using at the same time as adjuvants all other remedies conditions generally indicated for special purposes It neutralizes the wise acts specifically as a potent germicide, antisepammonæmia and superalkalinity of system, disinfects tic, antizymotic, antipyretic or febrifuge, antipyre,

and size of herbage, of which the first is the princi- and destroys zymotic, septic, contagious or infectious. nares, gastro intestinal canal, liver, lungs, blood, and body, promotes the normal secretions of the salivary glands, stomach, liver, bowels, kidneys, and other organs, depurates and purifies the fluids and solids of the entire system, quenches thirst, reduces fever, resolves abnormal conditions, and restores the healthy equilibrium of hæmatosis, circulation, nutrition, secrally, while at the same time it exerts a stimulant influence upon the brain and nervous system, or gives a "buoyant feeling," as a patient expressed it, invig orating and enlivening the whole being, body and

> Nitrohydrochloric acid is thus specifically potent not only in the milder disorder of a non infectious, scorbutic, and mephitic character, but also in the most malignant and contagious maladies, as typhus, ship, scarlet, puerperal, and like fevers, with small pox, diphtheria, cynanche maligna or putrid an gina, crysipelas, carbuncle, and other zymotic, sep tic, putrescent, and pernicious diseases. It is, hence, especially indicated in yellow, as in ship and cognate fevers, with other septic, infectious and malignant maladies, and may be given freely therein separately or in conjunction with other mineral, vegetal and animal acids or remedies indicated, and doubtless with as beneficial effects in the former as in the lat ter Besides other evidence which might be adduced of its superior value, this was clearly exemplified in seventeen or more cases of ship fever which came into the Philadelphia Hospital under my care at one The patients were seriously ill, spotted with the macula of typhus, and so offensive and conta gious that it was dangerous to go near them, yet with the free administration of vegetal and mineral acids, nitrohydrochloric acid being the principal, they were soon disinfected, purified, revivified, and restored to health, all recovering except one brought in moribund and dying before treatment could be In septic and toxemic states, with or instituted without local complications, as in malarial, bilious, remittant and other adynamic fevers, with lithæmia, scurvy and scorbutic conditions generally, benign or malignant, this acid is also a sovereign remedy li putrid, and diphtheroidal sore mouth, throat and ad Jacent parts, as it dissipates the disease rapidly It is also the basic and specific remedy for diphthena itself, with acetic, lactic citric and other acids, pepsin, papoid and other solvents of the fibro plastic membrane, and the active stimulants and tonics in Hydrogen peroxide is also applicable as a dicated germicide, antiseptic, antizymotic, disinfectant, te solvent, oxidizer, vitalizer and tonic in this dire af fection, with all other scoibutic, septic, putrescent, in As an oxidizer, fectious and contagious diseases vitalizer, alterative, resolvent, depurant, stimulant and tonic, nitrogen monoxide is also specially indi cated in diphtheria with asphyviating and adynamic Nitrohydrochloric acid like

disinfectant, depurant, lavative, diuretic, securnant, resolvent and tonic, in all forms and stages of scar latina, in destroying the germs and infecting princi ple or contagium, aborting and subduing the fever, preventing and correcting the inflammation, soreness and ulceration of the throat and glands, disease of the kidneys and resulting dropsy, with desquema tion of the skin, and in overcoming the toxicity of blood and system, promoting healthy renal, hepatic, and other secretions, and in restoring the normal ac tion of the bowels and state of health generally the malignant type of rubeola it is likewise benefi cial, but in the more active catarrhal form, with hard, dry cough, the neutral or alkaline salts are most ap propriate, either alone or in conjunction as indicated, the variety modifying the treatment in this as in Besides these pernicious anginose other diseases affections with septicity of blood and local compli cations, there are other allied maladies, as puerperal peritonitis and fever, erysipelas, and similar morbid states, in which it is very efficacious The use of nitrohydrochloric acid occasionally according to necessity during pregnancy, is especially indicated as an efficient antalkaline germicide, antiseptic, al terative, or chemico vital transformer, disinfectant, refrigerant, depurant, secement, laxative, diuretic and tonic, that will prevent, counteract or resolve the concomitant albuminuria, uremia, anasarca, and other senous ailments incidental thereto, and avert puerperal eclampsia and fever, with many of the mi nor ills of gestation, as it will preserve and restore the equilibrium of health, make the patient comfortable, and abort or break up the disposition to puerperal disorder of most kinds

Long since, in the Boston Medical and Surgical Journal, Vol xlvi, Nos 22 and 23, under the comprehensive title of "Anæmatosis," I treated of various analogous pathological states as similar dia thetic conditions, viz

Tuberculosis, Albuminosis, Adiposis, Glucosis, Toxicosis,

believing them all to be dependent upon the same general cause of a deficiency of oxygen, or more pre cisely, defective oxygenation of the blood and sys-Thus, while both albuminuria and glycosuria may be occasional, accidental and limited, and with deficient oxygenation, the kidneys acting as a sort of safety valve to free the vital economy from or allow the excess of unassimilated albumen and sugar to escape with other extraneous matters ordinarily, but which gradually or suddenly increasing beyond the normal limits and passing into the pathological state with the morbid manifestations pecuhar thereto in various degrees of intensity, until they finally culminate in pronounced disease of the severest type, with excessive loss of nutrient matter and conse quent irritation, congestion inflammation and disor ganization of the renal organs, similar to tuberculosis

Surgical Reporter This brought me a well known physician, Dr H, of a bilio lymphatic temperament, large and portly, rather past the meridian of life. who said that he had been afflicted with albuminuria for sixteen months, and was greatly despondent thereat, believing that he was incurable, especially as he had been declared by his medical friends. among whom was the late Prof Gross, to be a hopeless case of Bright's disease, in which he coincided In accordance with my idea of the general cause of this affection, viz, defective oxygenation, I recommended an abundance of pure air, and to insure this, to live an active out door life as much as possible, with corresponding hygienic measures, and moreover, advised him to take nitrohydrochloric acid as an antiphlogistic, antitoxic, alterative, resolvent, disinfectant, chemico organic transformer, oxidizer, vitalizer, diuretic, and tonic, as hydrogen peroxide, nitrogen monoxide, and ather sources of oxygen were not so convenient then as now, the albuminuria disappeared, and he recovered Gross met him some time after and expressed surprise at seeing him yet alive, saying, according to the rules of medicine he ought to have been dead six months before However, he lived for about eighteen years thereafter, even longer than his eminent confrére who had doomed him to an early death so many years be-This case affords an instructive lesson, as it strongly shows the shortsightedness of regarding seemingly remediless diseases as incurable, and doing nothing, or continuing in the old ruts to destruction, instead of working out some new course which may lead to conservation and recovery, especially when it is proven that many chronic, difficult, and so called hopeless cases can often be cured, or at least relieved, and life prolonged and made comfortable by judicious treatment, as the experience of scientific physicians so frequently testify, and the haphazard experiments of empirics occasionally illustrate to the discredit of legitimate medicine Such cases are often incurable only because we do not know how to treat them properly from the want of correct knowledge on the subject, and not absolutely or inherently irremediable This is strikingly exempli fied in the case in point, for here is an afflicted man, a physician himself, with his own life at stake, and presumably au fait with all the best treatment for relief as well as his medical confréres, doomed to death by all as a hopeless case of supposed incurain the physiological and normal line of health from ble disease, and yet recovers with very simple treat-Hence, in all such apparently irremediable cases, it would be better, guided by reason, to strive for relief and cure even under the most adverse circumstances, as I have seen cases the most uncompromising and seemingly hopeless, both acute and chronic, react and recover under appropriate treatment

But to return to the special subject of study lithemic, uremic, toxemic, chylæmic, or icteroid and bilious affections, defective and atrabile, gallstones, oxaluna, with other forms of lithiasis, and ammoniacal or alkaline urine, aneuria, constipation, Some time after, about twenty or more hæmorrhoids, hypochondria, pertussis, with analoyears ago, I reviewed the subject in the Medical and gous blood and nervous disease, both infectious and benign, dyspepsia, struma, syphilis, chronic rheumatism, and cutaneous affections of various kinds, degrees and parts, dependent upon or connected with superalkalinity and similar toxic states of the blood and system, defective or depraved secretion, etc., nitrohydrochloric acid is likewise very In the albuminuric, uramic, hepatic, cardiac, renal, puerperal, and other varieties of anasarca, or almost all forms and degrees of dropsy, it is very active in counteracting the underlying chemico vital derangement, restoring the balance of nutrition, with hepatic, renal and general secretion, producing diuresis, defecation, and in correcting the proximate cause of systemic disorder, removing its effects and reestablishing the healthy state of the en-It is inapplicable, however, where a tire economy calorifying alterative and diuretic is required, nitrous oxide being far superior as an oxidizer, vitalizer, chemico-organic revolutionizer, resolvent, stimulant, tonic and diuretic, curative not only of dropsy, but of a great variety of diseases and other abnormalties

In scrofulous and inflammatory states, eczema, herpes zoster, and other cutaneous eruptions, carbuncles, ulcerations, phlegmonous, gangrenous, purulent and suppurative affections generally, nitrohydrochloric acid is highly efficient as a resolvent and In acute inflammation its activity and value was strikingly exhibited in the case of a young lady of a nervo-lymphatic temperament, subject to that intractable ailment, periodontitis and alveolar abscess, whenever her blood becomes superalkaline Upon one occasion in the afternoon her teeth became loose and the lips and face rapidly swelled out of all proportions, accompanied with exquisite pain and suffering, threatening a general suppurative inflammation of the gums, integuments of the teeth and face, but by a liberal dose of nitrohydrochloric acid, ten drops of the dilute every hour to saturation, the superalkalinity of system was soon corrected, the disease conquered by the next morning and quickly subsided Nothing else was given or done, the acid being sufficient, and always relieving her Whenever the laxative effect of the acid is not prompt enough, a moderate purgative dose of citrate of magnesia may be added Moreover, by correcting the general dyscrasia upon which they are dependent, and acting as antalkaline, germicide, antiseptic, resolvent, alterative, tonic, etc, with soothing or appropriate local treatment, it also counteracts and discusses that malignant disorder, carbuncle, with its phlegmonous and gangrenous analogues Further, in that still more formidable general disease, variola, with its serious local lesions, and the extreme derangement of toxemia, pyemia, fever, inflammation, suppuration, contagion and infection, nitrohydrochloric acid seems to destroy the smallpox contagium, abort and overcome the fever, subdue the inflammation, prevent, shrivel and dry up the pustules, conquer the disease aborigo, and counteract and resolve the malady altogether, hence is especially adapted to the prophylactive and curative treatment of this dire pestilence, with all similar pathological conditions Other acids are also useful for the same purpose in varying degree

While either one of its constituents-nitric or hydrochloric acid, of this compound nitrohydrochloric acid, may have similar effects to a certain extent. they cannot separately fully exert the same influence as when combined, either in character, efficiercy or Other compatible acids mineral, vegetable. and animal, with acidulous fluids and fruits, as sour buttermilk, lemons, grapes, and edible tart things generally, may be used in conjunction therewith according to special indications, but of the general subject of acid medication and regimen I have treated some what fully in my work on the "Basic Pathology and Specific Treatment of Diphtheria, Typhoid, Septic, and Allied Diseases." In various complications of inflammatory, fibrous and plastic evudates, the neu tral or alkaline salts are useful adjuvants as solvents and discutients, as sodium and potassium chlorate. etc, while the acid is the main and basic remedy, with the more active stimulants and tonics

The constitutional effects of nitrohydochloric acid are produced by its external application in baths, ablu tions, etc., 'as it is absorbed, and is thus applied for the relief of various hepatic and other affections too well known to require further mention here. In cases of poisoned wounds and bites of irritated and rabid ani mals, I have been in the habit for many years of given ing with the best results, nitrohydochloric acid inter nally to counteract and destroy any toxic matter absorbed, as well as to apply it externally and chlor ine water or chlorinated soda with or without carbolic acid, to most effectually nullify and eradicate any venom which might be deposited or taken in, con tinuing them as freely and long as the patient desired to satisfy and quiet the mind with the assurance that the most effective measures internally and externally, had been employed for the destruction of infecting virus and the preservation of health and life Hydrarg bichlorid might be added both internally and externally, if thought necessary, with other ger micidal, antitoxic, alteratives, and disinfectants

Nitrohydrochloric acid thus affords a simple, safe, convenient, agreeable, expeditious, efficient and reli able means of disinfecting the living body of persons thoroughly, under the most adverse as well as favor able circumstances, as on ships at sea, at quarantine, in hospitals, and in private life, at any time with the least trouble and expense Although caustic and escharotic when concentrated it is innocuous when diluted, except when continued too long or fieely it may produce ptyalism and sore gums, hence should be occasionally intermitted in chronic diseases when ever anything of the kind threatens or occurs Otherwise it is agreeable to the stemach and system generally, and pleasant to take properly diluted, in from two to four drops of the strong or ten to twenty drops of the dilute acid every hour, two, or three hours, more or less frequently according to necessity In water, lemonade, infusion of barley, or other mild acidulous and bland liquid alone or sweetened to taste, it is an acceptable, antalkaline, germicidal, an tiseptic, antitoxic, disinfectant, refreshing, nutrient, restorative, and tonic beverage, very grateful and invigorating to those suffering with scorbutic, malan ous, hepatic, contagious, septic, febrile, infectious,

mephitic, and other affections As a nutritive diluent to promote its efficiency and increase the inges tion of acid, I usually give it with the juice of one lemon, in a goblet of sweetened water or other suitable menstruum, as freely as required and the stomach will bear, or if the quantity of fluid is objectionable, lessen the water and lime juice proportionately protect the teeth, it should be taken through a giass, clay, straw, or other non corrosive tube, and the mouth rinsed with lime, or other alkaline and plain water, though in edentulous children and adults it may be directly taken without such precautions, its localized action on the mouth being often desirable, always avoiding of course, its contact with metallic spoons, or other neutralizing and contaminating sub

In urgent and extreme cases, nitrohydrochloric acid should be pushed vigorously or given freely ad saturandum, to neutralize the superalkalimity of the blood and system, toxemia, septicemia, pyemia, uremia, and other pathological states, destroy the contagious and infectious principles, or germs, and resolve the concomitant abnormities as soon as possible, except in the extreme of Bright's disease, scarlatina, etc., wherein the kidneys are greatly disabled, when more discretion is necessary, so as not to throw it tends to resolve the renal disorder, restore the normal constitution, secretion and excretion of the urine, and excite diuresis, but in typhus, ship, yellow, bilious, malarial, and other fevers, variola, with the exanthemata, and other general and local diseases of a malignant, infectious or contagious, and scorbutic character, it may be given somewhat freely, unless the stomach is intolerant, when smaller quantities at shorter or longer intervals, by frequent sipping or sucking through a tube as it can be borne, according to indications or neccessity is more appropriate

In consequence of the cheapness and general efficiency of nitrohydrochloric acid it is peculiarly appropriate as a sanative and remedial agent for perlimited means, as well as the richer class. It is easily prepared by mixing gradually the two component acids-nitric and hydrochloric, in the proportion of three parts of the former to five of the latter, or of one to two, or equal parts of these acids, and after effervesence ceases to put and keep in a dark bottle in a cool, dark place, as it is apt to deteriorate from warmth, light, and time, hence it should be made in limited quantities, according to requirements When fresh it is of a golden yellow or orange color, and should not be kept long in solution sweetened with sugar or syrup as it is apt to form oxalic acid there with, a deadly poison, and of course, a dangerous mixture Therefore, to insure purity, avoid accidents, and otherwise, it would be to the interests of physicians to dispense it themselves in small quantities at a time as needed

I have thus presented a very general outline of the medical properties and applications of nitrohydro-

applicable to the prevention and cure of a wide range of abnormal conditions, both benign and malignant, local and constitutional, and affording a safe, convenient, certain and speedy means of resolving many serious diseases that now receive very complex, expensive, unsuccessful, and unsatisfactory treat-Therefore, I hope that this superexcellent medicament will be given a thorough trial and be put to the severest practical test by everyone having the opportunity to use it, so that the facts relating thereto may be more positively determined, for it is only by a multiplicity of observations and the experience of many recorded that the truth can be most fully established

116 N Fifteenth St, November, 1887

THE MORBID ANATOMY OF PERI-CÆCAL IN-FLAMMATION

Read before the Philadelphia County Medical Society, December, 14, 1887

> BY J H MUSSER, M D, OF PHILADELPHIA

Much confusion appears to exist in regard to the nomenclature of the inflammatory affections of the too much work on them suddenly or overpower them region we are about to consider. It may, therefore, with the materials of uriniferous elimination, though be well to state the meaning of the various terms which will be used in this discussion we shall understand inflammation of the cæcum, by peri-typhlitis, inflammation of the peritoneum covering the cecum, by para typhlitis, inflammation of the connective tissue behind the cæcum typhlitis is often used to include inflammation both of the cæcum and of the appendix We shall, as suggested by Dr Fitz, use the term appendicitis for inflammation of the appendix, appendicular peritonitis for typhlitis of the appendix and its serous covering, and para typhlitis for inflammation of the connective tissue around the appendix, or, if you please, peri-cæcal

It is well to know the relative importance of the sons in ships, quarantine, hospitals, and for people of inflammatory affections in this portion of the intes-Typhlitis has been considered by systinal tract tematic writers to be a frequent affection, and yet it is difficult for pathologists to find records of autopsies in which this condition has been found true that some writers, especially the Germans, have described cases, particularly of stercoral typhlitis, in which inflammation and ulceration of the mucous membrane of the cæcum, by pressure from fecal im paction, was present Most of us will, however, agree with Fagge that typhlitis is a good general expression used for all varieties of inflammation occurring in the right iliac fossa, but that in the majority of cases the correct term should be appendicitis Fagge relates a case of Williams' in which the patient had all the symptoms of peri-typhlitis with a tumor in the right iliac fossa. He was recovering from this when an acute affection of the pleura caused his death, and at the post-mortem there was found appendicitis, with ulceration and perforation, and not typhlitis. chloric acid believing it from my experience, to be of Dr Wilkes agrees with Fagge in this view, and they mestimable value as a sanative and medicinal agent, consider that the difference in degree of the inflammation alone accounts for the difference in the symptoms, | ner of making autopsy in such a case. There is and that the largest number of cases are due primarily to inflammation of the appendix

That inflammation may occur in the execum as it may occur in any other portion of the large intestine no one will deny But we can say from the records of Dr Fitz that perforation of the cacum is most rare, for in a most extensive research he was able to find but three cases, and in these instances, due to foreign bodies We shall, therefore, with Fagge, consider that appendicitis is the real affection that occurs in the region we are discussing (see Appen

A word with reference to the anatomy The cacum normally varies much in position as well as in shape On the blackboard are drawings of different forms of the cæcum, as detailed by Treves in his lectures on the anatomy of the intestinal canal He thinks that the cæcum is most frequently found, not in the right iliac fossa but on the psoas muscle itself, or in the pelvis, that the cæcum is entirely surrounded by peritoneum rather than only partially, and, therefore that behind there is no areolar tissue as was described by the older anatomists He does not believe, moreover, that there is a meso cæcum

It is also of importance to note variations in the appendix in the consideration of peri caecal inflam mation The usual position, as found by Mr Treves and by Dr Fitz, is behind the ileum and its mesen tery, with the tip pointing toward the spleen second most usual position is behind the cacum with the tip pointing upward Long appendices usually take this upward direction Fitz also refers to its lying on the psoas muscle with or without the tip in the pelvic cavity There are other variations in posi-It may stretch across the pelvis and become adherent to the sigmoid flexure of the colon, and in one instance I have seen the appendix in the inguinal canal associated with hernia In another instance it was adherent to a pyosalpinx (see Appendix, II) The appendix varies in size, it varies as regards the character of its walls, and it varies as regards its contents It may vary in length from one and one fourth to nine inches There is a famous specimen in which the appendix was nine inches in length It lay be hind the colon, reaching to the under surface of the liver (see Appendix, III) In cases dying from causes not associated with this region, the appendix is often found as a cord like body, having been the seat of previous inflammation. It may have a dilatation either at its blind extremity or in some portion of its length, especially pouch like at the mouth Sometimes the entire canal is dilated and filled with catarrhal products

The character of the contents is of importance Various articles have been found in the appendix, but chiefly fecal masses Seeds of various kinds, buttons, bristles, worms, shot, pins and gall stones have also been found It is in all probability on account of the presence of these foreign bodies that we have the serious secondary symptoms that arise (see Appendix, IV)

I shall next speak of the morbid anatomy of pericæcal inflammation

usually an extreme degree of peritonitis, and unless the post mortem is made with great care, it will be impossible to find the seat of perforation, if one exist. and the exact conditions and relations of the pen cæcal inflammation The casiest method is to begin at the first loop of intestine that is reached and from that unravel the intestines, separating with great care the adherent parts. If a source of obstruction is found, tie the bowel on both sides and examine the portion in situ, turning the gut if necessary Such an examination is absolutely necessary in order to

make a thorough study of the part

Inflammation of the appendix occurs both of the simple catarrhal and of the ulcerative type. That we have catarrhal inflammation we know from the lessons of morbid anatomy Clinically, it would be impossible to determine the presence of such an in flammation, however Catarrhal inflammation with succeeding ulceration, local peritonitis, and, finally, perforation, also occurs, and the following conditions are generally found after death. In the first place, on section of the abdominal walls there is found, especially in the right iliac region, an ædem atous state of the tissues, not only may there be serous ædema, but there may also be infiltration of pus, due to the burrowing from the primary abscess The peritoneum, if involved will exhibit an intense degree of inflammation with the characteristic injection, sometimes general, sometimes limited, and more particularly to the right iliac fossa and the pel vis (see Appendix, V) Serum will be found in the peritoneal cavity, and in some instances pus, blood is occasionally found. In the more severe forms, especially, large flakes of lymph cover the intestines, the parietal peritoneum, and the abdominal organs The intestines are also more or less adherent to each other, depending upon the duration and degree of The location of the abscess, for the inflammation it is usually circumscribed, depends upon the posi There are three positions in tion of the cæcum which it is most frequently found-either in the right iliac fossa just above Poupart's ligament, or behind the cæcum, or in the pelvis In a case which re cently came under my observation, the abscess was found in the pelvis, one and one-half inches below the level of the psoas muscle, four inches from the anterior superior spine of the ilium on the right side, and two inches from Poupart's ligament In another case the abscess was found behind the cæcum in the connective tissue of the right iliac fossa of the abscess varies, sometimes containing only two or three ounces of pus, and in other instances as much as a pint or more has been removed walls of the abscess differ according to its position In the first instance mentioned the upper wall was made up of the cæcum, the right of the pelvic wall, while posteriorily and on the left it was circumscribed The walls of the abscess by the adherent intestine may be made up by the intestines alone The appen dix is always found in the abscess, and has undergone changes varying in degree with the duration and se verity of the inflammation Inflammation and ulcer First, with regard to the man- ation of the mucous membrane, serous or purulent

infiltration of the walls, with perforative ulceration and encysted or localized peritonitis, are discovered and cannot be found, having undergone dissolution, The perforation varies in size, (see Appendix, VI) sometimes it completely surrounds the appendix, or even severs it in two, or it is sufficiently large to admit a probe only, while even in other instances it Sometimes two or more inflammation of the appendix can scarcely be detected perforations are found, and frequently they are covered by recent lymph The canal of the appendix We usually find in the canal, is very often dilated near the cocum, a foreign body, it may, however, be In the cases detailed by Dr found in the abscess Fitz, foreign bodies were found in 60 per cent other cases their presence or absence could not be positively determined, from haste at the autopsy, from their disintegration, or from their discharge into the bowel, so that the proportion is probably larger than There is one point of importance in refer ence to the surgery of this region, and that is, that the perforation usually occurs within one and one half or two inches of the colon Whatever may be the length of the appendix, the perforation is as a rule found at the point just indicated

There are, of course, many cases that do not ter minate fatally Under such circumstances resolution takes place, or the abscess becomes encysted, or the abscess ruptures into some neighboring organ Bernardy related a case to me where rupture occurred in the upper portion of the rectum and also through the abdominal wall of the umbilious Dr Edwards had a case in which fully one and one half inches of the appendix had sloughed off, the abscess ruptured into the bowel, carrying with it the portion of the appendix and a mass of grape seeds, which were dis charged together The abscess may discharge through the abdominal wall, through the scrotum, into the hip joint, through the loin or the perineum, or in other directions Sometimes the pus burrows up ward, even as high as and into the pleural cavity may say that the bladder is a favorite seat for the rup ture of such abscesses

That cure may take place in cases of perforation of the vermiform appendix, this specimen distinctly shows It was prepared by Dr William Pepper, and is in the museum of the Pennsylvania Hospital The patient died of another affection The appendix was cord like, except in one place, where an old perfor ation was seen, with organized blood clot and lymph

These are the chief points in regard to the morbid anatomy of pericaccal inflammation In the first place, that peri cæcal inflammation is due to the inflammation, ulceration, and rupture the appendix vermiformis with the secondary formation of an abscess, that the position of the abscess depends entirely upon the position of the appendix, that the further course of the abscess cannot be determined, that in the larger number of cases the inflammation and ulceration are due to the

appears to be as stated, and while it may appear to be a refinement of terms to differentiate between In some instances a portion has sloughed entirely off typhlitis and appendicitis, it is almost necessary in order that a correct and well defined appreciation of in others it is found as a soft mass of necrosed tissue the pathology be determined, so that early and proper Unless such a refinetreatment may be instituted ment be made, cases of this kind will be frequently treated as simple typhlitis, whereas in 90 per cent, or perhaps a larger proportion, they are cases of

APPENDIX

The following notes are presented explanatory in a measure of They are based on the appearance of the specimens the writer had on exhibition at the meeting, collected from priate sources and from hospitals Some twenty specimens were obtained for this purpose The writer's best thanks are due to Drs Pepper, Edwards, Bernardy, Willard, Woodbury, Long stretli, Ilinsdale, Seltzer, Daland, Bodamer, and others, for notes and specimens Some excellent descriptions may be seen in the catalogue of the museum of the Pennsylvania Hospital

I Strictly speaking, we should say the sequence of typhlitis, perity philitis, and peri creal abscess occurs but rarely A typh litis and perityphlitis, no doubt, are seen clinically, but the cases do not come to the post mortem table unless perforative appendicitis occurs conjointly For this reason, and because similar sequences of lesions does not obtain in similar inflammations of the large bowel under like circumstances, as fecal impaction from stricture, or from paresis in the aged or after typhoid fever, the pathologist may well doubt the existence of perityphlitis and succeeding peri crecal abscess In the more violent infiamma tions of the gastro intestinal tract, in gastritis, enteritis, or in dysentery, such sequential lesions are not found

II Case 1 - Matilda Thomas, at 104 years Cause of death, exhaustion of strangulated hernia Abstract from autopsy rec ord, Philadelphia Hospital Abdominal cavity, no effusion, adhesion of large and small intestine, appendix dilated to size of first finger, end of it incarcerated in inguinal canal, with po tion of mesentery and small intestine, so much post mortem discoloration could not determine color of parts, local peritonitis, in canal and layers of muscles and fasciæ consider able amount of greenish pus, the portions outside of canal ad herent to the bladder, uterus, and overy, the letter being in cluded in the inflammatory mass Organs occupy normal posi

Case 2 - Philadelphia Hospital Female, et 22 years Ap pendix four inches long, dilated to size of finger, contained mucoid

fluid adherent to a large pyosalpinx
III From Museum of Pennsylvania Hospital, described by (See a catalogue of Pathological Museum, 1869)

IV Cranberry seeds (Mears) Fecal concretions (Hartshorne, Daland, Hinsdale, Seltzer, Musser) Grape seeds (Edwards, W A) A concretion one half inch long and one quarter inch thick, cone shaped, apex pointing toward the perforation of the appendix, base concave, firm fecal color and odor, in mass of which black bodies, size of cranberry seed were found. It completely occluded the canal, causing retention of the natural se cretion inflammation, ulceration, etc. The perforation was cretion inflammation, ulceration, etc. The perforation was one eighth inch from the apex of the concretion (Musser). A

one eighth inch from the apex of the concretion (Musser) A phosphatic concretion in Mütter Museum (Woodbury)

V General peritoritis (Woodbury, Willard, Hall, [Mütter Museum], Bodamer, [Case I], Seltzer, Pepper [1637 Pennsylvania Hospital Museum atalogue No 136810], Meigs [Pennsylvania Hospital Museum catalogue No 136810], Meigs [Pennsylvania Hospital, 1366] Benardy, Musser] Local peritoritis [Mears, Pepper, Husselle Bodaper [Case a. J. Hartchorne, Musser]

Himsdale, Bodamer [Case 2], Hartshorne, Musser)
VI Two inches of the appendix necrosed, slate gray color, soft floated in the pus, attached slightly to the healthy stump Museer) Appendix sloughed off Mule, 40 years Periton its fourth day, (Bodamer, Case 1) Appendix one and a half inches long, ulceration one inch from bowel, a few lines in diam eter No communication between appendix and crecum Gela-timous mass in appendix (Bodamer, Case 2) Appendix removed by amputation, was attached by its blind extremity to omentum, also removed

Length two inches, one inch occluded by con presence of a foreign body occluding the canal—a cretions, and one dilated and empty (Woodbury, Mutter Mu retention inflammation The sequence of events seem) Appendix two and a half inches long Ulceration three

lines in length and two inches in width, half an inch from extremity Canal not dilated Walls not thickened (Willard) Mütter Museum, College of Physicians, of Philadelphia, A D Hall VA, excum and portions of ileum, peforation periton itis, death. When recently examined a perforating ulcer of the appendix was found, through which a grooved director could be passed, communicating freely with the peritoneal cavity. There are two perforations, one, 2 5 centimetres, from the caput coli, the muscular coating of the appendix appeared to have been de stroyed by ulcerations, and then the peritoneal coat had given way in three small openings about 2 millimetres in line. These

way in three small openings about 2 millimetres in line. These were arranged in a triangular manner. The second was a solitary perforation, 4 centimetres from the end of the appendix Although thick patches of lymph had been thrown out, no attempts to limit the effusion of foreign material by lymph barriers was discoverable. There was nothing to show that any foreign body or concretion or impaction had been the origin of the le Fluid pus was found in the interspace between liver and stomach, and about six ounces of turbid serum were in pelvic

Mrs C at 25 years, mother of two children, youngest four months old Death on fifth day of idiopathic peritonitis, with

The intestines were glued together

characteristic symptoms

Catalogue of Mutter Museum, College of Physicians, E. Harts Appendix, gangrene and perforations Recently ob served the appendix was inflamed and greatly enlarged, and intimately adherent to surrounding parts, was distended to a sac 5 centimetres long and 2 centimetres broad, and communicated by a small opening with the cavity of head of colon, walls thick ened, infiltrated with dark blood and serum, its peritoneal coat highly injected and covered with evudation, and the mucous lining showing traces of extensive inflammation, which had run into a superficial gangrene The latter had produced a honeycombed appearance of the inner surface, and had covered it with a dark greenish, pulpy, and extremely fetid matter On its side, about two thirds of the distance from the excal extremity, an ulcerated perforation, some 6 lines in length and 3 lines in width, was found, from which fluid feerl and other matter had been flowing in small quantities Immediately behind this opening, and encased by the appendix, a peculiar, moderately hard concretion, of the shape and color of an elongated olive stone, presented itself, having been apparently moulded by the cavity by which it was contained. This was in layers, and was probably hardened fecal excrement which had accumulated by slow oozing of the fluid contents of the large intestine through the small orifice of the distended appendix. No other evidence of morbid action in abdominal cavity, except congestion and ædema of ovaries and fimbriated tubes. Death on the fifth day from peritonitis

THE DIAGNOSIS OF PERI-CÆCAL INFLAMMATION

Read before the Philadelphia County Medical Society, Dicember 14, 1887

BY WILLIAM PEPPER, M D, LL D,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA

I fear that the remarks that I shall make may seem vague and desultory, for it is difficult to compress what is to be said within the very reasonable limit assigned I am quite willing to accept the terms suggested by Dr Musser, but I do not think that the term paratyphlitis, as indicating inflammation of the peri-cæcal connective tissue, is likely to gain general usage It is probable that the term peri typhlitis will continue to be used to indicate in flammation of the walls of the cæcum, and of the the cæcum and the peri-cæcal connective tissue, and neighboring connective tissue Still, anatomically and for purity of nomenclature, it may be well to recognize para-typhlitis, as indicating inflammation such cases of the peri cæcal connective tissue

are very striking I would merely add to these one resolution I have the records of scores of such

or two facts In the first place, the appendix pre sents evidences of a disease in a very large number of indifferent autopsies I remember the report of a series of 300 autopsies, in which there were signs of disease of the appendix in 33 per cent, although in none of these was there a history of typhlitis We have this little organ, singularly useless physic logically so far as we know, placed in a singularly unfavorable position anatomically, very liable to become impacted, so formed that escape of its contents is very difficult, and very prone to become dis-We must recognize the fact that the ap pendix is often diseased when we have no reason to suspect such a condition I cannot agree, however, that the cocum also is not often the seat of disease In a long experience in which I have paid much at tention to these diseases, I have collected a number of instances of independent cæcal disease, where the cacum alone presented lesions, sometimes going on to chronic inflammation, ulceration, and perfora The real condition of things seems to be this In the first place, there are many cases of mild ap pendicitis which cannot be recognized during life, in the second place, there are a considerable number of cases of typhlitis where the symptoms are chiefly due to inflammation of the walls of the cæcum and of the peri caecal connective tissue, which end in re It is impossible in these cases to determine covery what proportion has been due to appendicitis Finally, there are also a good many cases of severe appendicitis resulting in ulceration and perforation, with the formation of circumscribed abscess or of If we could accept the view general peritonitis that perforation of the appendix, leading to pen typhlitis or para typhlitis often resulted in recovery by resolution, it would be a matter of comparative indifference where the lesion was chiefly situated, but do clinical experience and anatomical records justify the view, that perforation of the appendix, followed by peri- and para typhlitis, often ends in resolution? It is true, that I have found one speci men, and that others have been placed on record where perforation of the appendix has not been followed by grave results, but do these amount to anything comparable with the great mass of cases where lesions of the appendix have occurred with peritonitis and fatal result unless relieved by opera It seems to me that we have to recognize that while in typhlitis, peri-typhlitis, and para-typhlitis, m all probability appendicitis always exists, yet it is often present in only a very mild degree, and can cause only a small portion of the symptoms This conception seems necessary to a correct diagnosis of these lesions, it is necessary in guiding our treatment

There appear, then, to be two classes of cases In one the affection is more limited to the walls of the appendix is affected to a comparatively slight We have no record as to the frequency of degree The record is not to be sought on the post mortem table, for the large proportion of these The anatomical points made clear by Dr Musser, cases, if properly treated from the beginning, end in

cases, the vast majority of which ended in resolution crecal region so terminating So large is the number that I cannot consider that in any large proportion of them did perforation of the appendix occur the initial symptom, not excruciating in character, nor associated with the evidences of collapse, often accompanied with nausea and vomiting, and with elevation of temperature, which continues to rise until decided fever is present. With these symptoms there is excruciating tenderness in the right iliac fossa, a sense of fulness and induration, not rarely with dorsal decubitus and flexed thigh, with a constipated condition of the bowels possibly pre ceded by one or two irritative movements during the first day, and with these there is considerable ac celeration of the pulse In proportion as the induration and swelling is early and marked, it has seemed to me that the chances are that the appendix is not seriously involved, but that the affection is chiefly one of inflammation of the walls of the cæcum and of the pericæcal connective tissue with exudation, and I have no doubt the fever may not rise very rapidly tion of the cæcum

from food and absolute avoidance of interference with the state of the bowels be adhered to, if local depletion be employed, if counter-irritation followed by if the convalescent is properly treated—that is, if mentioned these restrictions be insisted upon until the sensibil [induced when the stomach is taxed ity of the part is entirely removed of the convalescence from the primary attack of case

On the other hand, we know very well that such cases not rarely go on without resolving, that the invated and possibly are such as to indicate suppuration, and that at periods varying from seven to fifteen days pus formation occurs. Such cases de mand operative interference, and are successfully treated by the Parker operation The existence of five to ten days pus can often be demonstrated by exploratory punc ture with a fine aspirator needle

There is a second class of cases of an entirely op posite character, with which we are all equally fa Here the patient may apparently have been in almost perfect health, for perforation of the apof which the patient had complained But in these appendix, is no longer able to circulate and escape, group of cases

and the irritating frecal matter excite more serious I think the experience of those I address would inflammation in the walls of the appendix, ulcergive a large number of cases of inflammation in the ation is established, and finally, perforation occurs, and the symptoms of the attack begin rarely seen a fatal case of disease of the appendix I think where there was not stenosis of its orifice I have seen them, these cases are marked by pain as that, to a large extent, it is this tendency to closure. and the accumulation of the secretions and of fæcal matter, that causes the more serious type of inflammation and the occurrence of perforative appendicitis

The first symptom in these cases is usually intense and excruciating pain, so severe at times as to cause collapse, occasionally so severe as to be followed by death in a few hours Following this there is the rapid development of the signs of peritonitis pulse become frequent There is marked tenderness, not in the iliac region only, but also toward the middle of the abdomen The belly becomes distended, but there is no induration to be felt, there may even be no fulness in the right ileo cæcal region The appendix often lies under the cæcum, and I have frequently percussed these cases with great care without finding any evidence of dulness or of After the occurrence of the initial pain, induration There may be usually accompanied with considerable feecal impactionly moderate febrile reaction for one, two, or three days, associated with continued, moderate pain simu-If absolute rest be insisted upon, if abstinence lating an ordinary catarrhal attack with intestinal For two or three days these cases may be viewed as not being seriously ill, so delusive may be the symptoms after the subsidence of the initial pain the application of the ice bag, or warm fomentations In these cases there is absence of ileo cæcal infilbe employed, and if the internal use of opium and tration, or induration, or tumor, or prominence, or mercury be begun early, the vast majority of such dulness, on percussion There is in these cases a cases terminate in resolution and complete recovery less degree of vomiting than in the first class of cases The vomiting is often rare, and only The bowels I am satisfied are quiet, but not so obstinately constipated and that the well known tendency to the recurrence of not so strongly resistant to the action of laxatives as typhlitis is largely dependent upon the management in typhlitis, with more or less impaction of the Such cæcum After a time which varies with the intensity would seem to be the diagnostic marks of this type of the attack, and the direction which the exuded matter has taken, there appear the symptoms of a rapidly spreading general peritonitis. The belly becomes greatly distended and tender, the coils of duration extends, that the symptoms become aggra- intestines are outlined through the tightly stretched The vomiting becomes frequent, the temperature rises, the pulse grows thready and rapid, and we have the familiar signs of general peritonitis These cases end fatally, from exhaustion, in from

Here are two groups of cases which seem to me to differ not only in degree, but also to differ in the seat of their lesion and the character of that lesion I cannot believe that in any great number of cases of the first group there is perforation of the appendix Yet, unless perforation is present, we have seen that pendix may occur without any previous symptoms all the other lesions of the appendix may exist without the production of any symptoms Therefore, I cases there has been a catarrhal appendicitis, the cannot attribute to ordinary appendicitis the sympfæcal matter which is present in nearly every healthy toms of peri cæcal inflammation which mark the first These symptoms we must assign to because the outlet is partially closed by the swelling the inflammation of the walls of the cæcum and of of the mucous membrane, the pent up secretions the peri cacal connective tissue in chief part

It is, therefore, of momentous importance that we should be able to diagnose the sort of case that we have to deal with, and that at the earliest moment I should say, that in proportion as the tumor, prominence, induration, and dulness are marked, delay is safe, especially if rectal examination—the mention of which I have postponed until the last—does not indicate any fulness on the right side of the roof of If this is present, it indicates an amount of exudation which will end in abscess, and is a strong indication for operation If digital examination, pushed if necessary to the extent of the introduction of the whole hand, reveals no fulness in the roof of the pelvis, I think delay for several days is justifiable, and with such treatment as I have indicated, the symptoms will, in the majority of cases, subside, and although the case is fraught with great anxiety, resolution will begin, the symptoms will become milder, and the patient recover, and under proper treatment the part will be restored to absolute health without relapse Even if frequent relapse occur—and I have seen as many as fifteen or eighteen in the same individual—complete recovery may follow a protracted course of treatment with absolute rest, rigidly restricted diet, constant counterirritation, and suitable alterative treatment internally

Of course, if after waiting a few days, there is no evidence of the commencement of resolution, if the fever is sustained, particularly if it assume a hectic type, we know from experience that suppuration will not be long postponed Exploratory puncture should be made, and operation should follow without

The most important question to be considered is What is the earliest moment that we can establish the diagnosis? On account of the shortness of the time, I limit myself to the differential diagnosis between the two forms of cæcal inflammation to which The initial symptoms give us some I have referred indication of the seat and the gravity of the attack Typhlitis and peri-typhlitis soon offer demonstrable symptoms, but as the appendix is hidden under the intestine, the symptoms of perforated appendicitis are often obscure for two or three days The most careful palpation may fail to show the slightest ful- in particular, strive to point out the indications for The patient may complain of pain over the operation in the two classes of cases cæcum, or over the hypogastrium External examination does not aid us in the diagnosis any special features which will help us? I would been asserted that general peritonitis is not a contra again refer to the importance of the rectal examina-Early and oft-repeated rectal examination is the most important diagnostic means we possess in this class of affections Often, on opening the body after death, there is no appearance of peritonitis in velops death results under medical treatment the exposed coils of intestine There is no inflammatory process seen outside of the cæcum, and nothing is found until the cæcum is lifted up, when it is discovered that the inflammation is behind it, and extends downward to the pelvis Sometimes, on removing a layer of lymph, you disclose the occasion pelvis filled with pus In such cases, if rectal examination should give a sense of distention of the right side of the pelvic roof, might not a puncture be made with a curved exploring needle introduced

through the rectum? This has suggested itself to me, although I have never tried it. In this way we might demonstrate the presence of pus, when it would not be possible to do so through the external abdominal wall

In many of these cases there has seemed to be an unusual abundance of urine and an increased frequency of urination I think that the former is associated with the absence of vomiting and peri typhlitis, there is often so much vomiting that very little liquid is absorbed, and the urine be comes concentrated I have seen cases of perfora tion of the appendix, where the urine was voided at intervals of an hour or an hour and a half, the total amounting to a large quantity

Again, it has seemed to me that in perforation the pain is more apt to extend to the middle line of the abdomen, and sometimes into the genitals, especi ally into the right testicle and spermatic cord

The agony of pain which marks the initial lesion, the development of fever, the acceleration of the pulse, the distension of the abdomen, the pain refer red to some point in the ileo cæcal region, the com parative rarity of vomiting, the absence of induration and tumor, possibly, the ability to detect fulness or induration in the roof of the pelvis by rectal exam ination, the frequent micturition with a free supply of urine, the pain possibly radiating in the direction of the genitals, have, I think, been in the majority of cases, the most marked symptoms

Suppuration occurs in these cases very early, even earlier than in the other group of cases In one case in which Dr Keen operated for me early as the close of the third day, perhaps the earliest operation on record, a pint of pus was found in the pelvis

So much for the suggestions that I am able to offer with reference to these important affections The point to which we should bend our evertions, should be to determine the early diagnostic symptoms of these two varieties of cæcal inflammation, to see whether there is a constancy in the description that I have given of the first type of inflammation of the walls of the cæcum which, under proper treatment, We should, offers a considerable hope of recovery

I would ask if general peritonitis may not be a Are there positive indication for instant operation It has indication to laparotomy under other circumstances If this is the case, the development of general peri tonitis in a case of inflammation of the cæcal region would at once indicate operation, for after this de

I will not take up the question of the diagnosis of these affections from intussusception and internal Although this would be necessary for strangulation a comprehensive discussion of the subject, the time at our disposal will not permit it on the present

THE TREATMENT OF PERI-CÆCAL INFLAMMATION

Read before the Philadelphia County Medical Society, December
14 1887

BY THOMAS G MORTON, M D, SURGEON TO THE LENNS LIVANIA HOSPITAL

For practical purposes the treatment of perioccal inflammation must be divided into two subdivisions that of the pre purulent, and that of the post-purulent stage, or, first, before formation of pus or of appendix perforation, and, second, after that event

The treatment of the pre purulent, irritative, or simple inflammatory disorders of the execum and its surroundings, or appendix, should consist of rest in bed, restriction of diet to nourishing liquids, hot poultices or fomentations frequently replaced upon the parts, perhaps local depletion, and possibly the hypodermatic exhibition of morphia to control pain, whilst the bowels should be kept open and free from accumulation of gas and faces by the administration of salines and enemas—perhaps with the addition of turpentine to the latter

Those disposed to cavil at the advice just given I would ask. Shall we keep the bowels in liquid condition, and so prepared to best resist peritoritis, should it occur, whilst at the same time the mere draining of fluid from the intestines and surrounding parts would influence for the better the peri cæcal inflammation? or shall we paralyze, and congest, and inflate the bowels by the old fashioned "splinting" treatment, and thus beckon on peritoritis?

Pain of intense character would often be as much an indication for operative relief as for morphia

- Prompt resolution should take place in cases which are not to go on to the stage of pus formation, and very long continuance of symptoms, or relapses, or recurrences, would be strong indications for surgical interference

The presence of such tedious recovery, relapse, or recurrence would point to the probable presence of conditions exceedingly dangerous to the patient from hability to general peritonitis or perforation at any time, they further would point, as a rule, to the appendix as the source of irritation and danger. Indeed, in man, that worse than useless appendage must be regarded as the root of most evil in the region under consideration.

To illustrate this point by a single impressive instance, let me quote a case which was reported by me in the Philadelphia Medical Times, of June 11, It was that of a woman who for a long time, had been having mild attacks of abdominal pain, located in the region of the cæcum, which had usually yielded with great promptness to anodynes During the course of the last attack of that nature, violent symptoms of perforation and general peritonitis came I did not see her until two days after this un fortunate accident, but, though she was then in a most desperate condition, I advised operation as her only chance, and forthwith performed abdominal sec-The appendix was found perforated in two places, and violent general purulent peritonitis going She died a few hours afterward, but I felt better satisfied that the operation had been performed

Coming now to our second division, suppose the process to have gone beyond the simple, inflammatory stage, and the presence of pus, even a few drops, to have been diagnosticated

In the great majority of instances, the presence of even a minute amount of pus so near to the peritoneum would be of vastly more risk to the patient than that of abdominal section for its relief. Hence, I should operate whenever the diagnosis of pus had been made—occasionally even without positive diagnosis. But in this paper diagnosis of distinct conditions is presumed, and I am expected simply to outline treatment for those defined conditions, hence, without qualification, I repeat that, pus being present in the region of the cæcum, operation is positively indicated

Many other risks are to be taken rather than those of purulent peritonitis, for early interference will save most, if not nearly all cases from this latter dread complication, while the danger of operation becomes slight compared to that of rampant abdominal inflammation

Local or general peritonitis supervening in a person that has a history of cæcal trouble, or starting during a first attack, would more than justify operation

At a later, or even perhaps chronic stage of the disorder, all available diagnostic skill must be exerted when a peri cæcal abscess may have pointed in an anomalous situation, and we must ever adhere to the modern surgical rule, always to attack pus at its source if possible When the cæcum is normally placed, this is always feasible, if the disease be recognized

Coming now to speak of actual operative measures, the patient, as a matter of course, must be got into the best possible condition, and surgically clean by the usual methods of attempting these ends Asepsis should rigidly prevail throughout

The aspirating needle must never be used, for if it does not find pus we cannot be sure that none is present, whilst its own dangers are not inconsiderable. In these cases it is a poor and especially unsafe diagnostic resource.

The abdominal incision should be lateral, not median. For if median the peritoneal cavity would often be needlessly opened, and the cæcum and appendix cannot well be reached or dealt with through

It But if lateral it can be made of less size, circumscribed abscesses will frequently be found before the peritoneum is reached, and at its base all necessary manipulations can be made upon the cæcum, appendix, and surrounding parts without opening the peritoneal cavity, whilst should the abscess or ulcer have reached that cavity, the intestines, etc, can just as well be examined and cleansed through a lateral as a median incision

Attempts to reach the cæcum by the lateral or subperitoneal incision without opening that membrane will nearly always be found impossible to carry out, and even should the organ be so reached lesions cannot be properly dealt with at the bottom of such an opening

The favored or lateral incision should begin at a point an inch above Poupart's ligament and to the

outer side of the right linear semilunaris, be continued in a vertical direction upward about four perforation likewise should receive identical treat inches, and carried down through the parietal mus cles until pus, cæcum, or peritoneum encircling that region organ be reached if necessary cavity clean, and get a clear view and careful exam ination of the cæcum and appendix. The latter is almost always the seat of trouble, and perhaps it would be well to excise it whilst we have the chance in any case, for any cæcal trouble would be likely in time to excite disorder of its appendages Without ated a doubt it should be so treated if found inflamed, perforated, or harboring a foreign body best be accomplished by ligating it as close as possible to its excal attachment and cutting it off Cecal perforations, if found, should be closed by Lembert sutures, whilst ulcers, which may be present but have not perforated, should by the same means be turned into the bowel lumen If the general peritoneal cavity has not been involved, the abscess or crecum or what not in view should be gently curetted, washed out with a 1 to 1,000 bichloride of mercury solution, a large glass or rubber drain introduced, and the ab dominal wound closed around it with silk sutures, and a dressing superimposed

If the peritoneum has become involved and but a short time before the operation, the whole abdominal cavity must be most thoroughly washed out with hot to 110°) distilled water, or 1 to 10,000 bichloride of mercury solution, and cleansed with sponges, and the foreign body, if that has been the source of trouble, searched for Should peritonitis be found further advanced the intestines must be withdrawn, and all adhesions parted with the finger or knife during the process of cleansing, and before they are returned to the peritoneal cavity In the case of general peritonitis a glass drain must be carried to the bottom of the pelvis and kept in working order by means of absorbent cotton ropes acting by capillar-If a second tube is not used for the superficial or peri cæcal abscess cavity, the drain going to the pelvis must have perforations as high in it as the level of the cæcum and any surrounding trouble

If the inflammation should be caused by the presence of a foreign body in the cæcum itself or by im paction of fæces, they must be either excised or urged by prudent force along the bowel operative removal a simple incision, afterward united by Lembert sutures, would answer every purpose

If portions of the cæcum have sloughed or become gangrenous, and the breaches of continuity are too large to approximate with Lembert sutures without producing dangerous constriction of the gut, we will have to content ourselves with the formation of an artificial anus

Post-operative treatment would consist in keeping the bowels in a fairly soluble condition, the tube clean, and in meeting threatening peritonitis by active purgation

These same general principles of treatment will hold even for those rare cases of displacement of the cæcum as into scrotal and other herniæ, its abdominal transposition, etc, the great question in these cases to a paper read by me in the winter of 1877-78, be will be diagnosis

Typhoid caecal or appendicular inflammation or ment as for the simple inflammatory disorders of that This whole subject is still in its infancy so Then the wound can be enlarged far as the majority of the profession are concerned, If pus be found, wash its containing but the child is of almost boundless promise

> I can terminate this going over the field of cæcal inflammatory disorders, their pathology, diagnosis, and treatment in no better way than by showing to you the patient whose case was reported to you by Dr Woodbury in April last, and upon whom I oper He has been benefited as much by the practi cal application of the principles of treatment which This can have been laid down, as any human creature ever can be

FERRI OXYDATUM VERSUS FERRI MURIATIS TINCTURA

Read before the Cincinnati Academy of Medicine January 17, 1887,

BY WILLIAM JUDKINS, MD,

TA IROFFSSOR OF HILSSOLOCY, AND CLINICAL LECTURER ON GENITO UI INALY SUFCEPTY, CINCINNATI COLLEGE OF MEDICINE AND SURGERY, CINCIN ATI, OHIO

A short time ago, in the discussion following avalu able paper read before the Acadeny, I suggested the administration of dialyzed iron to children Ex ception was taken to the suggestion by a distinguishment guished member, claiming it was worse than useless (or words to that effect)

We have with us, "as in the medical profession at large and in other spheres of human thought and ac tion"—as a recent member of this body, with an in ternational reputation, remarked in a lecture a few days ago—"two opposing parties, the optimists ard pessimists, the orthodox believers and the Nihilists The former accept everything unhesitatingly, the latter deny everything and ask for proofs, but they do not apply the Socratic method further, for when the proofs are forthcoming they continue to deny" A position of mere negation settles nothing The scriptural injunction, "to try all things and hold fast to that which is good," is the true position for us to Hence I have thought it of sufficient im portance to call attention this evening to the relative merits of iron in the two modes of preparation, di alyzed iron, and the muriatic tincture, for it was the last formula that was advocated as preferable to that What do we have? In the one a of the dialisate neutral solution of oxide of iron, in the colloid form, the result of endosmosis and diffusion with distilled In the other a combination water, elegance itself of metallic iron, muriatic acid, alcohol, nitric acid, and water, repulsive to the taste, injurious to the teeth, of uncertain potency and benefit, of uses for one only, a so-called tonic With the dialisate we have a pleasant and tasteless combination, harmless to the enamel, of uniform strength, of marked effi cacy, useful as a tonic, astringent, as well as an ever ready antidote to that rapidly death dealing poison,

arsenic If you will pardon me I will call attention in part fore the Cincinnati Medical Society, an abstract of which appears in the American Practitioner for 1878, In that article mention is made Vol 17, page 294 of 19 cases, including some in the "Children's Home," which for the time was under my care, during the Those reported absence of the regular attendant cases were in infants from 2 months to 2 years and 9 months old, all of a diarrhæal nature were treated with the dialysate, and the results were uniformly the same, a complete restoration of the secretions of the alimentary canal within 24 to 48 Since presenting these cases, others in which the iron has been ordered have been seen time and again, not only of summer diarrhæa of children, but many cases also in adults

During the last few months of my service at the Home for the Aged, two gallons of this useful and pleasant form of iron were administered to the in mates of that institution, none of whom were under 60, many over 70, and not a few beyond four score, one being in her 98th year. At the time of my resignation, and when sufficient time had elapsed to show a change in their condition, all, with two exceptions, showed and proved marked improvement by their appetite, general condition and weight ceptions were due to negligence on the part of the nurse in one case, and to the neglect of the other patient to take his medicine The exact number and age. I do not remember, but the greater number were ordered the medicine, and most of them had suffered in early years from taking the acid prep aration of iron made by the old formula

Mention must be made of one case, a woman, æt 78 years, who had been an inmate but a short time when she was taken sick with her ninth attack of erysipelas in fifteen years The only medicine given | was dialysed iron, liberal doses were given every two or three hours, with the result, according to her account, of cutting short the attack some five or six days, and, in her opinion, preventing the loss of her hair, which heretofore had invariably fallen out when convalescing

One, if not the principle, objection to the muri atic tincture of iron, is its want of uniformity is only efficacious as a remedial agent after having been six months in preparation Several ethers develop in which the efficacy of the drug is found it is made now by a large number of druggists a cheap solution of ferric chloride is purchased and diluted, some even diluting the spirits This is due to the decline of legitimate pharmacy, and the rise of commercial manufactures I have found that all kinds of iron are used in the early steps of this manufacture, scrap iron, iron horse shoes, old iron, and in fact all kinds except the best cut iron wire has been asserted that if twenty samples of the tincture were taken and evaporated down, no two would be alike in the amount of iron scales left as a resi One sample was shown that was merely dinal preparation The nitric acid that is used, as a of dialyzed iron, he speedily recovered rule, is so highly adulterated that cases resembling

arsenic poisoning have been known, due to the impurity of that article

As an antidote for arsenic we have an ever ready and efficacious remedy in the dialyzed iron Thos B Reed, of Philadelphia, reported about the first case, now several years ago, in which a fatal dose of arsenic was taken by mistake, but the patient was saved by the prompt administration of di-Dr Wm B Hazard, of St Louis, Dr alyzed iron Crenshaw, of Richmond, Va, and others, have been successful in cases of arsenic poisoning by the timely use of this antidote

As to the value of dialyzed iron as a prevention to poisoning of those exposed to the inhalation of air impregnated with fumes of arsenic, I can give as proof of its efficacy an extract of a paper by Dr Bullard, of Wicks, M T, that appeared in the Medical and Surgical Reporter recently He says

"In the smelting of lead and silver ores, one of the worst features is the constant inhalation of arsenical fumes When first employed by the Alta Montana Co to take charge of their hospital, a number of cases of arsenic poisoning came under my observation, and they were the more difficult to treat on account of their complication with 'leading' I tried the various remedies recommended for such cases, with but poor results At times I felt that the old saying, 'throw physic to the dogs,' was but too true and applicable At last I was led to try dialyzed iron, and met in all cases with most gratifying success, as is evidenced by the following cases

"Two carpenters were engaged in roofing a portion of the smelting building, and were in such a position that the wind carried the fumes into their faces Some workmen below noticed one of the men swaying to and fro, and about ready to fall, while the other was laboring hard to reach the ground were helped to the hospital, and were suffering with severe pain in the stomach and bowels, nausea, vomiting, vertigo, and with a profuse nose bleeding, tremor in lower limbs, and almost prostration glassful of dialyzed iron was given immediately nausea ceased, and at the end of one hour the men It were able to walk to their cabins, carrying with them a bottle of the iron, to be taken in drachm doses, every half hour At the end of twenty four hours they complained only of weakness, such as would The second day they result from a severe diarrhœa resumed work, entirely free from all pain and effects of the arsenic A number of men employed about the smelting furnaces, and especially in dipping the molten lead, have been apparently prostrated by the effects of the fumes, and were in every case relieved by dialyzed iron A mild purgative was given within I have recommended and, indeed, intwelve hours sisted on every man who is exposed to the arsenical fumes taking a dose of the iron daily The consequence has been that we have had but one case of poisoning needing hospital treatment, and this one luted muriatic acid, with enough coloring matter to insisted that his case was one of indigestion and dysgive it the proper shade, so that it would be difficult pepsia, and would take nothing till compelled to for any but an expert to distinguish it from an offici- enter the hospital, where, under the administration

"In the past two years I think I am safe in saying

that fully 200 cases of arsenical poisoning have been cured in this camp by dialyzed iron I could cite any or all of them, with symptoms, treatment, etc, but I think it unnecessary, as they so nearly resembled those already mentioned, suffice it to say, that all experienced the nausea, griping, vomiting, muscular tremor, etc I have given the iron, in half ounce doses, three times daily, with no constitutional disturbances whatever, even after ten or twenty days' The teeth are not discolored, bowadministration els not constipated, and digestion not deranged

"The men have learned its virtues, and come regularly with 'please fill my iron bottle again' They will not do without it, any more than an Irishman will do without his salts and senna It has saved many a man his wages and many a day of sickness In fact, I feel convinced that this preparation is indispensable where men are liable to inhale the fumes

of arsenic

"Without a remedy of this kind, I am satisfied no man, however strong, could inhale the fumes incident to smelting, where the ores contain arsenic, and stand it more than three or four days. I can fully and confidently recommend this preparation of iron to the profession, and even to foremen of smelting works where there is no physician, for it is harmless and in-'An ounce of prevention is worth a pound of cure,' or, a 'pound of cure' is worth infinitely more to a company than are hospitals full of men poisoned with arsenic Our hospital has been built, medicines bought, physicians and nurses paid, and accommodations for thirty beds provided, inside of two years, by a small monthly assessment on each miner and laborer employed by the company, and all are satisfied, none more so than the smelter hands, who can and do get a 'bottle of that iron' and keep at work"

For the purpose of pursuing this interesting subject further, I procured a full-grown jack rabbit, and with the assistance of my friend, Dr John D Jones, President of our State Board of Health, administered Before compoisonous doses of the arsenious acid mencing, the animal was firmly secured and a barbed arrow introduced into the pericardium by which the heart's action was noted, 135 beats, full, per minute, One-half a grain was apparently the normal state was given per os, with the result of reducing the heart's action to 120 per minute, although no decrease in fulness was noticed In five minutes another dose was administered in the same manner, through a glass funnel, with the result of still further reducing the pulsations to 112, and making them Some convulsive movements somewhat less full The next dose was were manifested at this time given endermically, reducing the heart's action to 10 and quite feeble, convulsive movements more marked and some squealing At this time we administered 3 fluid drachms of the iron with an equal portion of water, and soon noticed an increase in the heart's action, and more quietude in movement 2 fluid drachms of the iron were again given, diluted with water, after an interval of twenty minutes, with the result of gradually bringing the heart's pulsations up Patient was placed under the influence of opiates to 130, but not quite so full as before the experiment and rested comfortably During the afternoon, as commenced

Though undoubtedly a poor subject, as we could only have the objective symptoms, the iron certainly gave the desired relief, namely cessation of the excessive convulsive movements and a return of the heart's action almost to what it was when the animal was running over the office floor, before commencing the operation

To still further convince any doubter, by letter and by personal inquiry I have been enabled to learn of a number of the active practitioners of our city who are in the habit of ordering this drug, among whom are Drs C D Palmer, G Bruhl, Thaddeus Reamy, Giles Mitchell, B F Clark, - McMehan, F Forchheimer, W H Taylor, R Sattler, J D Jones, N P Dandridge, - Schmidt, J T Whittaker, C G Comegys, E W Walker, Wm Carson, A G Drury and others.

In the East we find as earnest advocates of the use of dialyzed iron, such as Drs Weir Mitchell, John H Packard, and Wm Pepper of Philadelphia, and Emmet, who in his "Diseases of Women" (p 549), in speaking of fibrous growths says "In the treatment of two cases recently I have been particularly pleased with the marked improvement following the In both instances other forms use of dialyzed iron of iron had caused headache and constipation, and an unexpected loss of blood "

I trust that facts enough have been brought forth to prove the efficacy of the drug, and that a faithful trial will convince the most skeptical of its benefit to those under our charge I can but think that Henry O Marcy, of Boston, struck the keynote of truth "The landmarks of our fathers have when he said become of small value, in these days of careful inquiry and patient research, of radicalism and reform, little respect is now paid to dogmatic teaching truths are reexamined, sifted from error, and associated with new facts in such a way that new teachings are evolved, and the 'thus far and no further' of even our student days is no longer heeded "

MEDICAL PROGRESS.

PROLONGED SURVIVAL AFTER EXTENSIVE FRAC-TURE OF THE PELVIS -DR S D HOWARD, of Elk Grove, Cal, reports the following case On October 31, 1887, T W was working in a gravel pit when the bank, which rose above him about twenty A mass of earth, that must have feet, caved weighed about 300 pounds, struck him over the lumbar and gleutal regions, throwing him against the hub of a wagon wheel which impinged on the pelvis He was taken out by his companions and When seen half an hour brought to town in a cart later he was suffering from shock and complaining of intense pain in the right ileac region, any moveof the parts being attended with agonizing pain. An extended examination was impossible, I could, however, feel distinct crepitation on the right side, and concluded that there was a fracture of the ilium

he was unable to pass water, I introduced a No 6 silver catheter The instrument apparently entered the bladder without difficulty, but no urine escaped, blood, both fluid and in clots, came away quite ticemia 1 The bladder did not appear to be distended, and no further attempt was made until late in the evening, and then with precisely the same result The following morning the bladder was distended, and, though anxious to make water, patient did not appear to suffer greatly from this cause I again in troduced the catheter, but fuled to enter the bladder Blood came through the instrument, and during the night some had flowed from the penis I then be heved that the right kidney had been injured, and that the bladder was full of blood At noon that day Dr J H Parkinson saw the case with me tient was fully anæsthetized (on the previous occasions I had given chloroform to partial insensi bility), and examined The bladder was distended, reaching almost to the umbilious, the abdomen on Repeated attempts with either side was resonant various instruments completely failed to enter the It was noticed when using a large silver instrument, that the point had a tendency to turn to the right when in the neighborhood of the prostatic On this occasion, also, blood escaped freely from the passage As it was evident that the urethra had been lacerated, and that operative treat ment was imperative, he was removed to the County Hospital for better facilities

On admission, Dr White succeeded, without much difficulty, in introducing a catheter, but though several sizes were used, large clots of blood choked the instruments so that little urine was obtained was decided to perform a perineal section, and the patient was placed on the table and anæsthetized The patient being placed in the lithotomy position, a large double current catheter was introduced, when the urine flowed freely This rendered the opera tion unnecessary and the instrument was tied in, the bladder having been first thoroughly irrigated careful examination then showed that there was a fracture of the right pubic bone, crepitus being distinctly obtained with one finger in the rectum was also apparent that there was extensive laceration of the urethra, implicating the wall of the bladder The catheter was kept in position for four days, antiseptic irrigations being used twice daily this the instrument was withdrawn, the urine passing freely by the urethra The injections were con tinued-solution of corrosive sublimate 1 3000 at first, and, later, solution of carbolic acid 1 100 being employed Mucilaginous drinks were given freely with quinine and opium, the latter very freely broad band of adhesive plaster was passed round the pelvis and over it a muslin bandage During micblood, small shreds and muco pus passed away On November 10, patient had a chill, and on the following day there was cedema of the thigh November 12, the cedema was more marked, distinct fluctuation below Poupart's ligament and ex tending through the tissues of the thigh was appar-

on the outer side of the thigh, nothing but serum escaping On November 13, fourteen days after receipt of injury, the patient died, evidently of september 13

Autopsy -Made November 14, by Dr White Body emaciated, marked cedema of the right lower extremity, two incisions on external side of thigh On opening the abdomen there was evidence of general peritonitis, the omentum was congested, a large ecchymosis, representing blood, effused behind the peritoneum, extending completely across the The descending colon, throughout posterior wall its entire length and including the rectum, appeared The inferior margin of to have been badly bruised the liver had the same appearance, also the right The right kidney was deeply congested, but uninjured, and the urine in its pelvis and ureter was The left kidney was intact On prolonging the incision down to the pubis, separation of the symphysis was found to the extent of one inch tending the incision outwards to examine the femoral canal on the right side, a comminuted fracture of the transverse ramus of the pubic bone was exposed The bone was bare, one of the fragments projecting The anterior and superior wall of into the bladder the bladder was absent, its place being supplied by the adjacent tissue, the viscus contained a small quantity of grumous matter, some of which could be identified as fibrin, the walls were covered with black tenacious mucous, the parts having a greyish-There was a free communicablack appearance tion through the femoral canal, between the bladder and a cavity in the anterior and internal aspect of the thigh, extending downwards for about six inches, this contained urine, unhealthy pus and tissue debris An examination of the perineum and urethra showed that the membranous and prostatic portions were absent, being replaced by a cavity communicating with the bladder, and also with the cavity in the thigh, allowing a sound introduced per urethram to pass readily into the femoral canal Further examination revealed the fact that there was a comminuted fracture of the right ischium at its junction with the ilium, symmetrical fractures of the left pubis and ischium, also comminuted, and a fracture of the sacrum on each side, close to the sacro iliac There was no attempt at repair in synchondrosis any of these fractures The parts were subsequently removed, and, in the process of cleaning, it was discovered that the third sacral vertebra was fractured through its body, and that a vertical fracture completely separated the laminæ and spinous processes of the first, second and third vertebræ from their bodies -Sacramento Meaical Times, January, 1888

pelvis and over it a muslin bandage During micturition, and when the bladder was irrigated, clots of blood, small shreds and muco pus passed away On November 10, patient had a chill, and on the following day there was ædema of the thigh On November 12, the ædema was more marked, distinct fluctuation below Poupart's ligament and extending the result of the uncertainty of the uncertainty particular infection, gonorithæa, chancre, tubercle—and adduces five cases of what he calls "ulcus rodens urethræ" This consists of a process of ulceration

To relieve tension two incisions were made notes of the autopsy

which slowly and continuously destroys the walls of sero purulent nature the urethra but not the adjacent tissues It gradu- of the ulcer did not seem to be much inflamed, but ally extends from the urethral orifice towards the they were very painful to touch bladder, and only ceases when the whole extent has were numerous brownish red nodules, singly or in There is no tendency to new formation, nor to healing For a long time it gives rise to so little inconvenience that the patient is quite unaware that there is anything wrong until the occurrence of marked suppuration, or of incontinence of urine attracts her attention. On examination, the meatus urethræ is found covered with pus and studded with a number of uneven swellings, between which are deep fissures, and thus the canal is rendered deep, crater-like ulcer. All the ulcers were painful These swellings resemble pointed condylomata, are soft to the feel, bleed very readily when amination of the lungs showed dulness high up to touched, and often fill the urethra as far as the neck the second rib on the left, where bronchial breathing of the bladder surface is felt, and the canal is found to have become granulations of the ulcers and in the sputa many narrower towards the bladder, so that it seems to be tubercle bacilli were found conical in form, the apex of the cone being towards and the lingual ulcer were treated with a 10 per cent the bladder From the vagina the urethra and periurethral tissue feel thickened and infiltrated Four of Dr Landau's patients were undoubtedly syphilitic, and the fifth also had probably suffered from the gum nodules, and the lingual ulcer, and they The author considers the ulceration to be syphilitic in character, but he only looks upon syphilis as the foundation on which the ulcerative process —the exact nature of which is unknown—develops The prognosis, as regards life, is not unfavorable, unless the process extend to the bladder and the lileo cacal region became very painful. She was diskidneys become implicated But a perfect cure is never to be looked for, and complete cessation of the destructive process is very rare Scraping, followed by the application of lactic acid, is the lations, the ulcers on the mucous membrane were treatment recommended by the author Anti-syphi- healed, and the large ulcer on the tongue was litic remedies proved useless, but Dr Landau thinks they might be of service at an earlier period, combined with the local application of lactic acid -London Medical Record, Dec 15, 1887

LUPUS AND CUTANEOUS TUBERCUIOSIS-At the last meeting of the German Scientific and Medical Association Professor Doutrei pront read a paper on this subject, in which he said that genuine cutane ous tuberculosis has been observed but very seldom, and so far as he knows never in a case of lupus But he had recently observed and treated two such The first case was that of a woman, 36 years old, who had suffered from "glands" since she was 20 years old Two years ago a nodule formed on the upper lip, immediately under the septum mobile, and in a short time several similar efflorescences covered both cheeks During this time the first nodule grew into a large ulcer, and later small ulcers appeared on the mucous membrane of both lips, nodules on the gums, and a large ulcer in the middle The patient had a cough that was periodical at first, but afterwards became constant She was small, delicate, emaciated and anæmic the centre of the upper lip was a rather deep ulcer, about the size of a quarter dollar, and its edges were simple, and easily and quickly done, not needing undermined, and the pale, reddish centre of which anæsthesia to produce muscular relaxation, and no was covered with small, grey, nodule like protuber- assistance is required -El Genio Medico Quin urgico, ances There was a small amount of secretion, of a Oct 31, 1887

The edges and surroundings groups as large as a bean, they were soft and easily pressed in, and between them cicatricial tissue was Two flat ulcers, with serrated edges, as large as a bean, were on the mucous membrane of the lower lip, their bottoms were almost flat, and on them could be seen grey miliary prominences There was a similar ulcer on the upper lip gums were also affected, and on the tongue was a to touch, and interfered with the patient's eating Ex-If the finger is introduced a rough and a slightly metallic rhonous were heard The lupus on the face pyrogallic acid salve, and sublimate bandages I 1000 Galvanic cauterization was used several times a day on the ulcers of the mucous membrane of the lips, were painted twice a day with a I per cent sublimate solution This treatment had a good effect on the lesions of the skin and mucous membrane, but the patient grew weaker and the pulmonary affection spread rapidly, diarrhœa set in, and pressure on the charged from the hospital at the desire of her family At that time the lupus of the cheeks was cicatrized, the ulcer on the upper lip was filled with good granucicatrized, but meanwhile cavernous formation had begun on the left of the tip of the tongue

In the second case tuberculosis of the subcutaneous connective tissue also existed to some degree, and distinctly on the chin, the patient had advanced tuberculosis of the lungs, and the sputum was full of This form of skin tuberculosis is tubercle bacıllı almost always secondary, and seen in cases of advanced lung-tuberculosis around the mouth or the Slight abrasions of the mucous membrane afford entrance to the bacilli, which produce the mil-1ary nodules that eventually ulcerate - Deutsche medicinishe Wochenschrift, No 43, 1887

NEW METHOD OF REDUCING DISLOCATION OF THE SHOULDER -DR P F ABRIL inverts the usual procedure for reducing a dislocation downwards of the humerus, by fixing the bone and making the glenoid cavity descend on the humeral head is made to stand with a crutch in the axilla, the surgeon holds the hand of the affected side, and makes slight downward traction, the patient now lets his body down, as if he were going down on his knees, At and by the pressure on the head of the humerus it is Abril claims that the method is slipped into place

Journal of the American Medical Association PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published. All comentunications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM, IN ADVANCE SINGLE COFIES

\$5 ∞

Subscriptions may begin at any time. The safest mode of remittance Is by bank check or postal money order, drawn to the order of the under signed. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters

NITRITES IN ASTHMA

remedy that will give even temporary relief to so distressing a condition as that of asthma will be welcomed both by the sufferers from it and by the medical men According to the observations of Professor Fraser, of Edinburgh, in the nitrites we have a remedy that will relieve the paroxysm almost instantaneously He does not, however, claim that these drugs cure in the sense of giving immunity from fresh attacks This is not the first time the nitrites have been used for this purpose, but the cases cited by Professor Fraser emphasize their good effects

On reading the record of his cases one can but be surprised at the marvelous and almost intantaneous relief that his patients experienced At first the nitrite of amyl was administered by inhalation The patient to whom it was given was suffering intensely from the dyspnœa Two minutes after she began to inhale the drug the cooing, whistling and creaking râles disappeared and respiration was greatly relieved, but all the trouble returned as rapidly as it had been mitigated Repeated inhalations of the nitrate of amyl gave only the most flitting relief It was soon found, however, that the same drug administered by the stomach gave relief as quickly but of a much more permanent character For instance, 5 minims wheezing râles so characteristic of the trouble greatly relieved

In half an hour he was anxious to sleep, and rested comfortably through the remainder of the night

Similar trials with equally favorable fresults were made of ethyl nitrite, sodium nitrite and nitro glycerine In the cases described by Professor Fraser there was only one in which a second dose of the drug was needed. In this instance I grain of nitrite Two minutes after its adminisof soda was given tration the "wheezing was no longer audible, and the patient said he was 'quite easy'" The time relation of inspiration to expiration before taking the medicine was as one to two and a quarter, and four minutes after as one to one The patient remained comfortable for two and a half hours, and a little more than three hours after giving the first dose of the nitrite, as the breathing had again become difficult, 1/2 grain of the same drug was administered with equally prompt good effect, and this time there was no relapse

As regards the administration of the nitrites Professor Fraser seems to show preference for the sodium compound Nitroglycerine he found was apt to produce headache, which did not accompany the administration of the sodium nitrite The latter in one instance when administered in the dose of 5 grains showed slight toxic effects Usually 1 to 3 grains were sufficient to give relief

While we have dwelt thus upon the therapeutic value of Professor Fraser's experiments, for they seem to us the most important results of his work, we would do him injustice did we not call attention to his own conclusions from them They were instituted with the hope of throwing light upon the mode of production of these dyspnœic attacks Taking into consideration especially the two theories, the one of spasm of the bronchi, the other of active dilatation of the bronchial blood vessels and consequent stenosis of the bronchi, he reasoned that the nitrites as they dilate blood vessels would increase the dyspnæa if the second theory was correct but if the first was right would probably relieve it, acting upon the unstriped muscle fibres of the brenchi as they do on those of arterioles He therefore urges that his observations confirm the belief that spasmodic asthma is the result of contraction of the muscles of the bronchial tubes Certainly the bulk of evidence of all kinds points to of amyl nitrite were given to a patient with intense the correctness of this view, but we must differ from dyspnœa whose chest was filled with loud cooing and Professor Fraser in estimating the value of his obser-In vations with reference to it For as is well known thirty seconds the râles were diminished, and in one and as he himself states, the nitrites cause relaxation minute the patient declared the breathing very of the blood vessels throughout the body, and lowers In less than two minutes the blood-pressure Why then may they not, as it were, breathing was easy and the râles were infrequent deplete the vessels that may be over-filled in any one

organ or tissue by withdrawing the blood into the general circulation? Indeed his own sphygmographic tracings show high arterial tension before administration of the nitrites which is at once greatly lowered but which returns with the return of dyspnæic symptoms

It would be an interesting experiment to try the effect of the nitrites upon a case of urticaria when very considerable active dilatation of blood vessels occurs through the action of the vaso motors, a condition closely analogous to that claimed by many to exist in the bronchial tubes in asthma

WANTED-A DEPARTMENT OF HEALTH

The calling of a convention to meet in Washington on January 19 to discuss the subject of food adulteration is another reminder that this country has existed long enough without a Department of Health It has been and is proposed by some to establish a Bureau of Adulterations, at an expense of not more than \$50,000 for the first year By others it is proposed to turn the business of looking up and preventing food adulteration over to the Internal Revenue De partment, in case the tobacco tax be repealed have a law respecting the adulteration of tea, and have official inspectors of tea under the Treasury Department The amount of good work that is not done by these official inspectors is shown by the amount of adulterated tea that gains admission to the country every year, to be consumed or detected and thrown out by local boards of healtn The proposition to place the Internal Revenue Department in charge of food adulterations in case of a repeal of the tobacco tax, presupposes something that is exceedingly improbable and for which there is no good reason, and assumes that men whose duty has heretofore been to see that all tobacco was properly taxed will be capa ble at once of taking hold of the enormous question of adulterations of food

There is no good reason for suggesting that a special department of public health should be buried in a department of the Government that is entirely foreign to the whole matter, or for thinking that the public health of this country can be properly attended to by two or three scattered bureaus in dis similar Departments of the Government deny that this country has as much need of a Department of Health as a Department of the Navy Certainly there is a more pressing need of having some form of administration that will keep cholera, yellow fever and other diseases out of the country than of repelling hostile human invaders Our Navy, study of the law and to graduation in the Law De-

such as it is, is kept for possible future emergencies, we need a Public Health Department for pressing present necessities and dangers The country has been and is too often placed in jeopardy by the carelessness of irresponsible State Boards of Health, ignorant commissioners and so called experts inland States have repeatedly suffered from outbreaks of preventable diseases, on account of the gross carelessness of the health officers of the coast States, this would be obviated by a Government Health Depart-The coast States and cities have been placed in peril by diseased food from the inland States, this could be obviated When a manufacturer of impure food stuffs is prevented from selling his adulterated articles in one State he can still sell them in States in which there is no stringent law or supervision, this could be obviated As the matter now stands one State may quarantine or detain against cholera or yellow fever a sufficient length of time, while the health officers of the adjoining State make insufficient quarantine or detention, thus practically destroying the efficiency of the health regulations of the first State, this could be obviated by a Department of Public Health One State has regulations in regard to the heating and lighting of railway cars, and their sanitary conditions, while three or four other States through which the same railway may pass utterly disregards such matters The matter of vital statistics is alone large enough to require a special bureau, as is also the matter of construction, ventilation, and drainage of buildings

There is no ground for fear that a Department of Public Health, once established in this country, will be long idle for the want of something to do

CLARK GAPEN, until recently a well-known and highly esteemed citizen of Madison, Wis, made us a pleasant call yesterday, during which we learned that he had changed his residence to Chicago, and entered upon a new and important field of professional labor Clark Gapen graduated in medicine in the Chicago Medical College in 1875, and after serving one year as interne of the Cook County Hospital, he became the resident physician at the Wisconsin State Hospital for the Insane near Madison, the duties of which he discharged with marked ability for three years, after which he pursued a successful general practice of medicine in Madison, and at the same time became Professor of Medical Jurisprudence in the University of Wisconsin, which position he still holds

His interest in this department led him into a full

partment of the University And now, with a thorough knowledge of medicine rendered more complete by three years of direct care of the insane and nine years of general practice, he adds a full knowledge of the law, aided by ten years of active teaching of medical jurisprudence, he has taken his position as a member of the Chicago Bar, and is prepared to give special attention to those numerous and important cases, the adjudication of which involves med ical testimony and the application of the rules of medico-legal investigation. With a thorough practi cal knowledge of both professions, and mental capa city of a high order, he will readily become one of the most useful and successful members of the legal profession

Condition of the Crown Prince -A cablegram of January 15, says "From high medical authority it is learned that there is now no reasonable question of the recovery of the Crown Prince" It seems that Dr Howell, who is in constant attendance upon the Crown Prince at San Remo as the representative of Sir Morell Mackenzie, administered specific remedies with the idea that the affection was specific It is asserted that the Crown Prince's condition be gan to improve almost immediately under this treatment, that the profession is now accepting Dr Howell's diagnosis and treatment as correct, and that it is thought that the Crown Prince will probably be cured

SOCIETY PROCEEDINGS.

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, December 14, 1887

THE PRESIDENT, J SOLIS COHEN, M D, IN THE

Drs J H Musser, William Pepper, and Thos G Morton, read papers on

THE MORBID ANATOMY, DIAGNOSIS, AND TREATMENT OF PERI CÆCAL INFLAMMATION

(See pp 69, 72, and 75)
DR W W KEEN said I remember very well the first autopsy that I made in private practice, twentyone years ago It was on a patient that had died of typhlitis without operative treatment, and the question arose in my mind at that time, whether or not a surgical operation might not have relieved him This was in 1866 In 1867, Willard Parker, of New York, practically systematized the operation Since then,

I should like to say a word or two with reference to the diagnosis I have seen many of these cases, and I have yet to see one in which a distinct tumor was As a rule, tumefaction will be found, but Nor is any fluctuation found in these no tumor In a case which I saw in consultation eight years ago, there had been extensive infiltration in the right iliac fossa, for three weeks, but there was absolutely no tumor and no fluctuation, yet, when the cavity was opened, a pint of pus was found should make up our minds positively, in reference to the surgical treatment of these cases, that we are not to wait for the formation of a distinct tumor or the presence of distinct fluctuation

Another symptom, to which Dr Pepper alluded, I have not found a constant one-and it is surprising that it is not-that is the flexing of the right thigh Not only may this be so, but all the other symptoms may be fading, and yet pus be present In the Medical and Surgical Reporter for the early part of 1886, I reported a case in which I operated on the sixth The symptoms had followed the ingestion of a large quantity of grapes, the temperature reaching The fever and pain had nearly disappeared, and the other symptoms had ameliorated to such an extent that convalesence seemed almost established. Here the diagnosis and treatment hinged upon one measure, which I was rather surprised to hear Dr Morton condemn—that is the use of the aspirator He, however, did not speak of the hypodermic syringe, and I do not know whether or not he includes that in his condemnation In these, and certain other cases, I think the use of the syringe for exploratory purposes is strongly to be commended I grant that it is not always safe to use the smallest of the needles of the aspirator, but to the use of the hypodermic syringe I see no objection whatever If it penetrates any normal structure, it will do no harm, and if it reaches pus, it gives a positive indication for opera-

The time at which pus forms is often extremely I have had two cases in which on the sixth day a large quantity of pus was found Both of these cases made excellent recoveries. In the case seen with Dr Pepper, pus was found as early as the close of the third day

I was glad to hear Dr Pepper refer so strongly to the importance of the rectal examination in these Others have alluded to this, but the urgent importance of it has never before been seriously dwelt upon Dr Musser has shown that the appendix often lies directly on the brim of the pelvis the perforation be near the cæcum, the pus will find its easiest outlet, in not a few cases, toward the cavity of the pelvis It is, therefore, in the majority of cases, within easy reach of the finger, and, in an urgent case, if it cannot be reached by the finger, the introduction of the hand, provided it be a reasonably small one, may be practiced

Both Dr Pepper and Dr Morton have alluded to operation in these cases As is well known the operthe sense of the profession in general has been more ation of Dr Willard Parker consists of an incision and more toward the operative treatment of these not vertical, but parallel, to Poupart's ligament This incision will do very well in the majority of cases, where the lesson is situated in the right iliac fossa Either this or the vertical incision to which Dr Morton alluded, may be selected As we go further and do not find pus, the hypodermic syringe may be used for purposes of further exploration the second class of cases alluded to by Dr Pepper, where there is perforation of the appendix, where there is absence of induration in the right iliac fossa and especially if there is a general peritonitis, I should certainly favor median and not lateral lapar-The latter does not give so simple and bloodless an operation, nor does it give us so easy access to the cavity of the pelvis for exploration, for drainage, and for the surgical manipulations that may In the case I operated on one year be necessary ago, for Dr Pepper, I regret that I did not do a median operation at once, instead of doing the lateral operation The median operation will give us every facility for operation on the viscera in the right iliac fossa, and especially will it give us access to the ap-Unless the indications for lateral operation found in subjects in the dissecting room be strong, I should favor the median incision

I should hesitate to perform puncture of the rectum It would be far better to do a laparotomy, rather than in the dark, not knowing what the lesion was, simply to drain the cavity of the pelvis, as we would do by We want to know what condition rectal puncture exists, we want to find out the exact facts Exploratory operation is not only constantly done, but done I may almost say, without any additional risk to the patient, and it gives us the means of dealing with whatever lesson we may find. If the appendix is perforated, we should ligate it and remove the dis If the cæcum should prove to be the eased portion the seat of perforation, we should close the opening If the perforation, is too with the Lembert suture large for this, it will be necessary to follow the plan suggested by Dr Morton, and make an artificial anus

The suggestion has been DR W HUNT said made that treatment with salines should take the place of the opium treatment in these cases, especi-This is a point on which more foration of the appendix ally after operation experience is needed before we can reach a decision When we take into consideration the fact that several cases of perforation of the appendix have been known to get well under the opium treatment, as proved by post mortems long after, and also the fact that the mortality after the adoption of that treatment years ago, fell to a large extent, we should not hastily between these cases and appendicitis, for the ma-It is no wonder I feel kindly toward it, pority recover for I am told that I am indebted to the opium treatment for my recovery from an analogous lesion—i e, perforation of a typhoid fever ulcer

A word with reference to the operation of ligating symptoms and cutting off the appendix It seems to me that by this method it might possibly be found that only mucous surfaces had been brought into contact and ulcer of the cæcum adhesion not secured It would be better after removing the diseased portion to close the stump by the Lembert suture

gion There can be little or no doubt that the cæcum | charged very freely In the third case the perfora-

-namely, that portion of the large intestine below the orifice of the ileum—is, in 95 per cent of all cases, absolutely free In the one hundred cases analyzed by Treves, there was not one meso cæcum If he had examined five or six hundred cases, he might have found two or three I have the records of many instances in which the cæcum occupied the classical position and was surrounded by peritoneum only on the front and sides, and last week in two cases in succession a well developed meso cæcum was present

It is remarkable how large a number of cases of appendix disease recover. I have carefully gone over my notes, and I find six cases of obliteration of There had been peri cæcal inflammathe appendix tion with subsequent obliteration. I find a record of eleven cases of ulceration, seven in phthisis and four in typhoid fever I have never met with foreign bodies in the appendix, but I have on two occasions had foreign bodies brought to me that had been

The important point in connection with perforative appendicitis, is that in the majority of cases the perforation occurs first with slight inflammation in the neighborhood, perhaps lasting a few weeks or months, without exciting any special symptoms, and the first symptoms to which the attention of the physician is called, and which are rapidly followed by peritonitis, are those of perforation not of the appendix, but of the appendiceal abscess In five instances of peri-cæcal abscess which I have examined, in every one of them there was evidence that the abscess had lasted some time That this is the case is evident from the fact that there are many instances-of which I have had three-in which there was no perforation into the peritoneum, and no peritonitis occurred, yet there The perforation had led were signs of septic fever not to general peritonitis, but to inflammation of the portal branches and diffuse abscess of the liver This is a point which, I think, has not been sufficiently recognized in dealing with these cases of per-

With regard to cæcal disease, we have all seen the cases which have been described by Dr Pepper think that they result, in the majority of instances, from impaction, and that the induration which we feel is in most cases fæcal is, I think, evident Dr Pepper has said, it is important to distinguish We, however, learn from postmortem examinations that a considerable number of cases of perforation of the appendix also get wellcases, too, in which there have been no special

I have had three cases of pen-cæcal abscess from disease of the cæcum Two were cases of round In both the cæcum was the only part involved, the ulcer not being larger than a quarter of a dollar In both instances the perforation was posterior and had excited suppuration in DR WM OSLER said I should like to make one the tissues as high as the kidney In one instance or two remarks bearing upon the anatomy of this re- the abscess had been opened in the loin and had dis-

There was in tion was due to cancerous ulceration this case a large perforation just beyond the orifice of the thum

DR J C Witson said I should like to indicate a division of the subject which I have not thus fur heard mentioned Dr Pepper has alluded to the form of inflammation which is so common, and which A large pro is probably due to frecal impaction portion of these cases recover, and the anatomical condition present must remain, to a large extent, in I am disposed to regard it as a local enteritis involving the crecum, and, perhaps, the appendix I believe the fulness that is present is due in part to fecal impaction, and in part to plastic exudation around the bowel

In the second place, we have those cases in which there is the formation of peri crecal abscess more or less limited in extent, and in course of time this will

require surgical interference

The third group of cases is that in which there is more or less extensive and general peritonitis, and this peritonitis may be due, as Dr Osler has pointed out, either to rupture of a pen excal abscess or to primary rupture of the appendix, with the escape of its contents into the peritoneal cavity I believe that in this form we have to deal with two essenti In the first place, we have ally different processes those cases in which we have rapidly developing peritonitis as the result of the escape of the contents of the appendix, or of a pen crecal abscess, and these cases demand the surgical interference which has been indicated to night I believe that there is another class of these cases in which the peritoneal process results, not in purulent exudation finding its way down into the pelvis, but in plastic exudation from the beginning Here we have the typical symptoms of general peritonitis without the forma-These cases, I am led to believe from tion of pus my own experience, not only terminate in recovery, but do better without than with surgical interference

Dr J S Neff said The early period at which pus formation takes place in these cases has been referred to I would only mention a case which illustrates the rapidity with which general peritonitis may appear I made a post mortem on a child which was struck with a stone, causing rupture of the bowel Death occurred seven or eight hours after the ac cident, not from shock, but from general peritoneal inflammation

DR E MONTGOMERY said I have met with a number of cases of these affections It is certainly difficult to decide what should be our plan of treat-We save cases in which this trouble exists, and goes on to local peritonitis, and under proper under my observation treatment recovery occurs We have other apparently similar cases, which end fatally under the same treatment Three cases have come under my ob One was a man some 20 years of age, who complained of severe pain in the right iliac in guinal region, with considerable tympanites, and with symptoms of peritonitis Leeches, followed by hot poultices, were applied, and morphia adminis symptoms began to subside On the morning of the on the coils of intestine

eighth day he had a severe lancinating pain in the side, with collapse, followed by death a few hours-The post mortem revealed gangrene subsequently This had been circumof the end of the appendix scribed by plastic exudation. At the time that the Inncinating pain had occurred, an artery had been opened, and hæmorrhage had occurred, which broke through the exudation, and a pint of blood was found in the peritoneal cavity

The second case I saw in consultation thirty six hours before the death of the patient, who was a man 50 years of age There were marked signs of peritonitis, with great distension of the abdomen, greatly interfering with the breathing. It was not deemed advisable to operate. As there were con-It was not stant efforts at vomiting, I introduced the stomach This was followed by the regurgitation of half of black material This gave considerable tube a pint of black material relief from the distress, and the abdomen was much On examination, perforation of the reduced in size appendix was found

The third case was one of those reported to-night,

in which operation was performed

I have now under treatment a patient 17 years of age, who, during the last six months, has had eight or ten attacks of tenderness in the right inguinal Although he has been in bed for the past three weeks on a restricted diet, he is now suffering from another recurrence of the symptoms question whether or not in this case it would not be better to do a laparotomy for the purpose of remov-

ing the appendix when the inflammation subsides

OR E T BRUEN said The treatment of peritoneal inflammation by salines is receiving considerable attention at the present time From what has been said to night, it would seem clear that in the treatment of typhlitis the important measures are those which secure rest, including the use of opium and the avoidance of all violence, and when the inflammation has subsided, the removal of the impaction by such mild laxatives as calomel, and, besidesthis, the treatment of the catarrhal condition by appropriate measures

In those cases where there has been rupture of the appendix, with the occurrence of peritonitis, it seems improbable that the administration of repeated doses of salines would be likely to do much good that the expression of medical opinion as to the measures to be employed under these circumstances

should be clear

Dr J H Packard said I would briefly refer to one or two of a number of cases illustrating the sub ject of this evening's discussion, which have fallen

The first occurred in the practice of the late Dr I. F Meigs, in 1860, and is reported in detail in the American Journal of the American Sciences for 1861. At the autopsy, made by me, an intestinal concretion had been lodged in the appendix vermiformis, and had caused a circular band of ulceration, at one point of which perforation had taken place was a collection of pus about the appendix, and unitered hypodermically By the seventh day the acute versal suppurative peritonitis, with flakes of lymph

Another case, which occurred in 1879, in my wards at the Episcopal Hospital, may illustrate the conclusion I do not deny that typhlitis occurs, I difficulty of diagnosis sometimes met with in these cases before the recent advances in the surgery of this region had been made of age, who had worked on a farm, was admitted on the colon may account of lameness, ascribed by him to ulceration of his right heel by a heavy and ill fitting shoe There was a swelling in the upper part of the thigh, which was regarded as a sympathetic bubo. At the lower part of the abdomen there was also some fulness and tenderness, which should have attracted more attention than it did, and which ought to have suggested the true nature of the case Several openings occurred below Poupart's ligament, the discharge was very abundant and soon became facal in A little later, fluctuation was noted above the ligament Parker's operation was performed, and a small angular piece of beef-bone was found that had worked its way out of the bowel more radical procedure, such as would now be resorted to, might have saved the life of this patient, who died exhausted

As to the employment of the hypodermic syringe for diagnostic purposes, it seems to me that if fluctuation is clear enough to warrant this, its aid is scarcely needed there are on record several cases in which fatal fæcal extravasation has followed the puncture by this for the inebriate means of a herniated bowel

With regard to the choice between the lateral and median incisions, I think that where the trouble is clearly in the right side of the abdomen, this is the proper surgical entrance If there is no necessity for opening the peritoneum, it is certainly sufficient And if there is such necessity, a lateral incision eight inches in length, such as is recommended for other purposes by several surgical writers, will give abundant access

I would suggest that in women a vaginal examination may enable us to explore the iliac lesions as well as the ovaries and tubes

DR W W KEEN said I do not wish to be understood as advocating indiscriminate laparotomy in I attempted to cases of peri-cæcal inflammation draw a distinction between those cases in which the pus is evidently in the iliac fossa, where the lateral incision is the proper one, and those cases in which examination by the rectum, and the vagina in women, shows that the pus has not been limited to the iliac fossa, but is in the cavity of the pelvis, where a median laparotomy is the better operation

DR C WIRGMAN said I rise merely to emphasize one symptom mentioned by Dr Pepper, and that is, the extension of the pain into the genitals I had one case in which the pain radiated down the inner and outer aspects of the right thigh case, which terminated fatally, the autopsy showed a concretion, but no foreign body I had cautioned the utmost quiet The patient was, however, a restless child, and on the eighth day flung himself from one side of the bed to the other This was at once followed by excruciating pain, for which it was necessary to administer ether

DR Musslr said I have but a word to say in wished simply to emphasize the relative importance of appendicitis as compared with typhlitis A boy, about 17 years litts may occur just as inflammation in other parts of

I am glad that Dr Osler referred to the relations of the peri cacal abscess to the peritoneum. In my hurried remarks, I neglected to mention it It must be borne in mind that the danger of a peri cæcal abscess depends entirely upon its relation to the peri-When intimately connected with it, or rupturing into the peritoneal cavity, the danger becomes imminent

INTERNATIONAL CONGRESS ON INEBRIETY.

Held in London, England, July 5 and 6, 1887

The Congress opened on Tuesday afternoon, July 5, with a reception to Dr T D Crothers, of Hartford, Conn, and other Americans who were present A large number of medical men were present, and after a service of tea and coffee the President, DR NORMAN KERR, took the chair In a welcome ad-It must not be forgotten that dress he said that to America we were indebted for the modern movement on behalf of special legislation From the illustrious Dr Benjamin Rush, one hundred years ago, to the present day, American physicians had laid the foundation of a great work of permanent reformation and cure sides the incalculable services of the United States in the rise and progress of the general temperance reform, and in the practical application of enlightened and effective prohibitory legislation, the recognition of the diseased state of many drunkards, and the consequent necessity for remedial treatment as in the case of other diseased conditions, had been first fully and persistently pressed in the United States In that great and friendly community across the Atlantic special institutions had first been established for the cure of the disease of inebriety The results had been excellent, and such as filled all their hearts with joy and thankfulness In England we were far behind the United States in this practical and useful There, the mebriate, willing to surrender his liberty, was deterred by no forbidding appearance before two justices from applying for admission to a The applicant could be re-Home for Inebriates ceived at once, and detained for the period for which he contracted with the managers by simply signing an agreement There, too, the long-suffering and harassed friends of the inebriate could, on proving his inebriety, have him compulsorily, if necessary, sent to a retreat for a time for care and treatment Dr Kerr had seen in America the most satisfactory issue from such commitments, Provision, too, was made for the poor Here we had no legislative pity on the destitute drunkard or on his sorely tried wife But the future was not without hope A better day was dawning, an auseven in Britain picious prospect for which we were mainly indebted to such pioneers as Dr Parrish, Dr T L Wright,

and Dr Crothers, who honored the Society with stant, social or solitary their presence that day

He concluded by offering a resolution of wel come, which was responded to by DR CROTHERS, in a review of

THE STUDY OF INFBRIFTY AND INFBRIATI HOSPITALS IN AMI RICA

He described the origin of the study of inebriety from the physical point of view, the hospitals for inebrintes to day, the inmates of hospitals and the cures, legal control of inebriates, the organization of State and private asylums for inebriates, the literature of mebriety and its peculiar character in America, and some general conclusions from this

DR JOSEPH PARRISH, of Burlington, N J, ad dressed the Congress on the inquiry

IS THERE A CHIMACTERIC PERIOD IN INFBRIFTY?

The author said that the climacteric cause of puberty and the menopause were well known In many inebriates there were periodicities, often referred to the gastric region, dependent on the condition of that part of the brain which presides over digestion Might not this periodic state exhaust itself at the time of life when vital force began to wane? From 500 cases, he had come to these conclusions that the majority were at the onset of the disease the subjects either of disease or accident, and had a tendency to peri odical outbreaks, others had a deficient resisting At what time did the morbid state antecedent to mebriety tend to exhaust itself? When the vital energy failed in intensity with the approach of age and altered conditions—between 45 and 50 years of age, sometimes sooner Besides direct alcoholic heredity, the union of incompatible elements in parents engendered in the offspring an unstable temper-

DR T L WRIGHT, of Bellefontaine, Ohio, read a paper on

THE EFFECTS OF ALCOHOL ON THE BODY AND MIND

He described at some length the two great classes of moral degeneracy from alcohol that arising in consequence of hyperplasia of the interstitial tissue in the brain, and that induced by long continued an-The symptoms in the progenitor, while presenting the characteristics of debased morality, may be attended also by some indications of insanity, while in the descendant the heredity is manifested by moral degeneracy only, and a consequent crimi nal proclivity, without symptoms of intellectual in

The opening Address by the President, DR Nor-MAN KERR, was delivered at Westminster Town Hall, on Wednesday morning His topic was

INEBRIETY, AND ITS MEDICAL, MORAL AND LEGISLA TIVE TREATMENT

He said that inebriety was a disease of the nervous system allied to insanity, and characterized by an almost overpowering impulse to, or craving for, the oblivion of narcotism—a true intoxication mania, or, as he preferred to call it, narcomania The disease

The form might be determined by complicating disease or correspond to the In alcohol mania, as well as apiritumebriant used ous there was wine and beer inebriety, though many who declared that ardent spirits were poisonous taught that wine and beer were innocuous, an extraordinary and perilous error, for nearly 10 per cent of the cases treated at the Dalrymple Home had been beer or wine narcomania Causes were predisposing and exciting An exciting cause provoked the mebriate paroxysm in a constitution predisposed to inebriety, while the same excitant had no effect in stimulating a person who had not this predisposition to excessive narcotic indulgence Among the predisposing causes the chief was hereditary, which was at times crossed, r e, the male children only of an inebriate mother labored under it, or the female children of an inebriate father Of exciting causes. some kind of nerve shock was the chief Inebriety had recently spread considerably among children, little ones of even 3 and 4 years, on recovering consciousness after insensibility from an accident asking imperatively for gin and other liquors The importance of a knowledge of the causation of inebriety lay in the basis this offered for sound treatment Quacks and philanthropists had sought for and had proclaimed that they found magic potions to charm away inebriety All these nostrums had been found Others had put forward vegetarianism as a cure, but its pretensions were also unfounded There was no royal road to temperance There were certain conditions of sound treatment The first was the unconditional withdrawal of the poison, which must be immediate with alcohol, chloral, ether, and chloroform, but should generally be gradual with The second and third condiopium and morphia tions were the removal, if possible, of the exciting cause, and the reparation of the physical damage wrought by inebriety, the remedying of the pre inebriate morbid condition, and the strengthening of the moral control The results of the treatment at the Dalrymple Home had been most satisfactory, more than one-half of the cases having been restored to their friends and to society The experience of other genuine homes had been somewhat similar third of the male cases might fairly be considered cured, the result not being quite so favorable in the case of females After a reference to the unfavorable legislation which existed in other countries with regard to this matter, the President concluded by declaring that they might hopefully look forward to a future time, whether they lived to see it or not, when the truth would be acknowledged by the Church and by the State, and full justice would be done to the physical infirmities of the weakest and poorest of ınebriates

DR CAMERON, MP, took the chair and addressed the Congress on

THE FORMER TREATMENT OF INEBRIETY,

saying that as lunatics used to be treated like wild beasts, so till recently habitual drunkards were regarded but as a nuisance to be got rid of by drinking assumed varied forms It might be periodic or con themselves to death. Only of recent years had it been seen that inebriety was often as much a disease as lead poisoning or the gout, and as susceptible of | Society of New York, read a paper on control and cure

DR DE COLLEVILLE, of Paris, France, read a paper on the

CONTINENTAL LEGISLATION FOR INEBRIATES,

saying that in Austria, Belgium, France, Germany, Greece, Holland, Italy and Switzerland, drunkenness was not in itself an offense, but public and disorderly drunkenness was punished by short imprisonment and fines In some countries the fines were increased by the number of convictions In some places bankrupts and paupers as well as interdicted persons, for prodigality, were not allowed to enter a drink establishment for thirteen months or more, as at Lucerne and in Galicia, except for food in necessity Diunkenness was spreading beyond the northern Continental regions, and Italy and Greece were becoming infected He concluded with a hope that the physical state of mebriety should be recog-Then all would have more common ground to begin on

LORD DENMAN, of the House of Lords, addressed the Congress and said that he had taken a great deal of interest in temperance, but not total abstinence When the rights of minorities came to the fore those who had advocated these principles year after year would have some respect shown to their efforts was satisfied that the disease of mebriety must be recognized, and physicians must teach us the real He would have the laws enforced strinremedies gently, and hoped a new era of the subject was close at hand

The REV J W HORSLEY, late Chaplain of Her Majesty's Prison, Clerkenwell, read an interesting paper detailing his observations on

INEBRIETY AMONG PRISONERS

He said that as there had been 20,000 admissions annually to Clerkenwell Prison, inebriety was constantly before him In ordinary prisons at least half the inmates would be in prison directly through drink, and another fourth indirectly In Clerkenwell many who were on remand or awaiting trial had not had time to get sober when he saw them, and were enter ing upon a recovery from delirium tremens were plainly dipsomaniacs, and then suffering from the circumstantial or periodic drink crave His estimate of 75 per cent of crime directly and indirectly due to mebriety was confirmed or exceeded by other gaol chaplains or governors, by magistrates, and police superintendents At one court he had found in one week 124 charges for drunkenness out of 154 Prison officials had clear proof of the popular fallacy that drunkards "must be let down by degrees" Thousands of cases every year proved that even in old standing cases sudden abstinence was quite safe A clever doctor whom he ministered to for three months, before hanging, said the imprisonment was a blessing, for he could not or would not cure him self of the morphia habit, and now through prison All prison doctors, when asked he was a free man what evil they had seen arise from the sudden disuse of alcohol, replied "none"

MR CLARK BELL, President of the Medico Legal

THE RELATION OF INTEMPERANCE TO INSANITY

In the course of his remarks he said that they might safely assume that science recognized throughout the world the abuse of alcohol, not only as the greatest and most direful cause of insanity known to the race, but that it recognized alcoholism in its various forms as a distinct type of insanity. The mission of the English Society for the Study of Inebriety was of the highest importance. If by their labors they could benefit the future humanity by a better understanding of the causes which had led, and were tending to the degeneracy of mankind, if with such knowledge, they could arrest or lessen the ills of inebriety, they would have accomplished a great good.

Surgeon-Major R Pringle, of the Bengal Army, in his paper on

HOMICIDAL AND SUICIDAL INEBRIETY,

observed that careful study of the disease in all its diseased conditions was essential to the devising of thorough and intelligent legislation now that heredity and environment were bearing their harvest Suicide and homicide, the result of alcoholic stimulation, were often but manifestations of a diseased cerebral condition which might be dormant through life, or, if lighted up by alcoholic stimulation, might exhibit themselves in murder or self destruction, or the angry blow of the partially inebriate. In confirming one of the sentences of death in India, Sir Lepel Griffin lamented the absence of a medical history of the accused, attaching no importance to alleged spiritual This is the true ground These cases delusions were cases of physical disease, and ought to be treated as such It is high time that some legal protection should be granted to the public in these diseased and easily provoked cases of inebriate, homicidal, and suicidal mania. This victim paid for his crime with his life, but the true cause remained unchecked and unnoticed

THE PRESIDENT read a paper on

COLONIAL LEGISLATION FOR HABITUAL DRUNKARDS.

He briefly reviewed the provisions existing in the colonies for inebriates It was only fair to say, he remarked, that there was as yet very limited accommodations in special homes for inebriates in the colonies, a practical haven of refuge and a means of restoration to health for the narcomaniac, which was much more abundant here We had a number of such homes for the well-to do, though none licensed It was high time that under our Act for the poor the Legislature of the United Kingdom should take a lesson from her vigorous colonial offspring by caring for the destitute as well as for the rich diseased drunkard, by offering an opportunity for the treatment of every mebriate willing to give up his freedom for a time, and by investing the proper authorities with power to compulsorily seclude the victim to narcotics for the threefold purpose of effecting his cure, of saving his wife and family from a life of inexpressible sadness, and of protecting the community from the violence and riot of a morbid maniac

AFTERNOON SESSION

DR B WARD RICHARDSON explained the

ACTION OF THE HEART AND CIRCUIATION IN THE INFBRIATE CLASSIS,

by sphygmographic tracings, which demonstrated that there was a deviation from health in every stage of inebricty. In the inebriate the heart was never The pulse read allowed to declare itself naturally produced the disease they called inebricty, the centre of which was in the heart and circulation In treat ment time and total abstinence were essential only must the alcohol be thrown out of the system, but it must be kept out till the perverted body came back to its natural state. A clear definition of the physical nature of the evil was essential

DR PETITHAN, of Liège, read a paper on

LEGISLATION FOR INEBRIETY

Alcoholism in Belgium has augmented with frightful rapidity, and calls for immediate action England and the Netherlands, these two classic countries of progress and liberty, and France had adopted repres-Belgium ought not to lag behind sive measures At present the alcoholized man, unless in extreme insanity or violence, is not dealt with He is not responsible, being under the power of alcohol, and yet has the control of his family, the administration of his affairs, and he is a juryman He cannot be interdicted unless he is mad, yet he has lost his will, is no longer free, and no more responsible newly discovered disease-inebriety-ought to be recognized by the law The mebriate should be hable to interdiction, not only by his family, but by a public officer This can be done now only in the event of fury or imbecility, but it can be done in a The alcoholized man, when his dislucid interval eased state is medically and legally recognized, ought to be interdicted. When he is interdicted there ought to be power to shut him up in a special home, where he should be treated, and obliged to work ac cording to his strength

Dr Axel Dickson, of Sweden, read a paper on

ASYLUMS FOR INEBRIATES IN SWEDEN

In Sweden there are two such asylums One is at Bic under medical superintendence, where the charges can be afforded by only the economically The other is for working people, at ındependent Tornas, the charges varying from £11 to £22 per The patients have to work on the farm, in the dairy stables, and elsewhere on the premises One year's residence is required No intoxicants are The farm has been open for only six allowed Already there have been seven patients, months some of whom are hopeful cases

Professor Binz, of Bonn, read a paper on

GERMAN LAW ON INEBRIETY

He stated that, by the German Penal Code, whoa condition in which, through the interposition of the of neuritis court, foreign help must be resorted to for his sup- dyspepsia, atony and degeneration of the mucous

port or the support of those whom he is in duty bound to muntain, is punished with imprisonment On a repetition of the offense, imprisonment can be arranged in a workhouse for a longer time closing hours of drink places are usually 10 o'clock PM in the country and II PM in towns

DR MOLITER read a paper on

INEBRIFTY IN BEIGIUM

He traced the history of the movement for legislaings showed continuous irregularity of the circulation for inebriates in Belgium, particularizing the tion. When the changes became permanent they labors of Drs. Petethan, Barella, Carpentier, Jansen, and others Dr Carpentier had found 90 per cent of his post mortems on males and 10 per cent of his post mortems on females at the Brussels Hospital show signs of incurable organic alcoholic disease The ages at which these mebrates had begun to drink ranged from 55 years to 8 years In Belgium they were agitating, r, for interdiction of the inebriate, 2, for seclusion of the inebriate in a special asylum for treatment of his disease Dr Moeller was in favor of the Government opening such establishments, rather than their institution by private indi-Inebriety was a true disease, and required not only medical treatment, but also legislative care and control

DR LEWIS D MASON, of New York, read a paper

THE RELATION OF DISEASE TO ALCOHOLIC INCBRIETY

Disease might act as the predisposing, exciting, or complicating and protracting cause of alcoholic ine-The disease might be inherited or acquired Of several hundred cases under his observation, over one third had either insane or inebriate parents, the latter being in excess In addition, all neurotic tendencies were predisposing, all hereditary diseases accompanied by degenerative changes, congenital syphilis, tuberculosis, epilepsy, or other neuroses These were born with a defective nervous system, and had a low resisting power to disease which tended to still further degenerate their nervous system Such were congenital neurotics, with a natural tendency to stimulating and narcotic drugs, readily becoming insane, or mebriates, or opium habitues, on the presentation of an exciting cause

Having pointed out the relation of disease or injury as predisposing or exciting to inebriety, let us now see how alcohol excites disease Alcohol is no respecter of tissue, though it is more deadly in effect on some structures than on others It is especially injurious to the cerebro spinal centres It acts on the cerebral vessels, as seen in vaso motor paralysis, in fatty degeneration of the capillaries, and leakage of the watery constituents of the blood, constituting serious apoplexy, a not uncommon fatal termination Epilepsy is a neurosis due to alcohol in inebriety About one in fourteen, in several hundred cases, were due to alcohol as the exciting cause there are various forms of acute and chronic alcohol mania, mania a potu, delirium tremens, chronic alcohol mania, and chronic alcoholism There are also ever surrenders himself to drinking so as to fall into general paresis, hemiplegia, and the multiple forms Alcohol causes gastric derangement,

coat and glandular structure of the stomach, a condition often secondary to hepatic derangement Phthisis is also produced by alcohol

CHEVALIER MAX PROSKOWETZ DE PROSKOW MARS TORFF read a paper on

INEBRIETY IN AUSTRIA

The author stated that in Austria inebriety was increasing everywhere on a dangerous scale consumption of alcohol (taken as at 100 per cent) was 67 litres a head in a population of 39,000,000, but in some districts 15 5 litres was the average (4 5 litres go to a gallon) In all Austro Hungary there was an increase of nearly 4,000,000 florins in the cost for alcohol in 1884-85 over 1883-84 there were 195,665 different places (stations, ginshops, and subordinate retails) where liquors were Dr Julius Wolff had shown that the proportion of liquor stations to the inhabitants varied from 1 for every 173 to 1 for 1,181 In districts where the most spirits were used there were fewer fit re Of 2,742 murders and homicides in Austria in .876-80, 978 were by drunken persons, in Bohemia, 103 out of 435, and in Moravia, 74 out of 242 Austrian inebriety was increasing in country and in 33 41 per cent of the insane in the Vienna Asylum were from alcoholism, or seven times more than ten years ago Alcoholism and inebriety had spread more rapidly since spirits had been made from molasses, potatoes, sweet turnip, Indian corn, etc Inebriety was also causing graver diseases The Aus trian Inebriety Society has asked the Parliament to establish homes for inebriates By the Austrian Penal Code (1852) accidental intoxication exempted from criminal responsibility, but it was an aggrava tion if the person knew from experience that he was very emotional when intoxicated Inveterate drunkenness was a misdemeanor in craftsmen working on roofs or with materials easily inflammable Austrian workmen generally take spirits at breakfast ducers of spirits into factories were severely pun In the Tyrol, C Payer says that two-thirds of the people are mebriates, including women the request of the Inebriety Society, the common Imperial Minister of War had requested command ers of troops and garrisons to ensure the sale by sutlers of tea and coffee at low prices The author had asked Parliament to teach the intolicating nature of alcohol in schools The Austrian Inebriety Soci ety was founded on January 17, 1884, and had done good work by collecting statistics, publishing pamphlets and proceedings, chemically examining spirits, and promoting tea cars and coffee rooms

DR EDWARD C MANN, of Brooklyn, N Y, read a paper on

THE PATHOLOGY OF INEBRIETY

He said Let the profession regard inebriety in its true light as a physical disease amenable to treat ment, and aim to instruct the communities in which they practice medicine as to the physiological action of alcohol on the functions of the human body, and the science of preventive or State medicine will owe an incalculable debt of gratitude to them for disease and death prevented, and much domestic misery averted

Inebriety is a disease caused by heredity by defective nutrition, by emotional shock, by physiological crisis, by visceral diseases, and by structural changes in the brain We may have anæmia of the brain in inebriety, with the blood in the capillaries deficient in quantity and defective in quality, we may have secondary atrophy of the brain, we may have hyperæmia of the brain, with increase of quantity of blood in the capillaries, with symptoms of either excitement or depression. We may have cedema of the brain, with infiltration of it and of the pia mater with serum, especially when the case of inebriety is associated with Bright's disease bral substance itself is not infiltrated In these cases we see a slow diminution of mental power and motor We may have softening of the brain from vascular obstruction, depending on vascular degeneration, causing thrombosis, or valvular disease of The former in mebri the heart causing embolism ates is the usual form, and it is associated with chronic alcoholism and Bright's disease generally the premonitory symptoms of mental dete rioration numbness, pains in the limbs and pains in the head, in the brain softening of inebriates sequently we see mental dulness, defective perception, drowsiness, loss of memory, slight delirium, emotional attacks, headache, articulation and handwriting bad, the delicate motor acts badly performed, and less of physical power Dementia may end the

Finally I would speak of the great importance of the recognition of the mental condition that in inebriates is the precursor of actual insanity I have had the opportunity of studying carefully several such cases, many of whom I have been so fortunate as to restore to home and society The clinical manifestations which I have observed in these cases have been depression, unwonted excitability, disregard of the minor proprieties of life, a change coming over the warmest affections, quick changes and rapid transitions in the current of the feelings, sleeplessness and a complete change of character and habit, the person meanwhile entertaining no delusions, but occasionally losing his self control, the general acts and manner at such times being strongly expressive of There are intervals of perfect the inward emotion calmness and self control, during which the person clearly discerns his true relation to others, and even, perhaps, recognizes the influence which the incipient disease exercises over his feelings and actions those cases where insanity appears, we see the utter downfall of the intellect manifested by the fury of mania, or the moodiness, suspicion, depression, and impulse towards self destruction of melancholia All these are the successive links forged in the chain of the insanity of the inebriate, the study of which is full of interest, not alone to the student of mental pathology, but to everyone who desires to lead the wandering mind out of the darkness and mazes of disease back into the light of reason

DR ALFRED CARPENTER read a paper on

THE VICE AND DISEASE OF THE INEBRIATE

Inebriety in its confirmed state is a disease

Ву

becoming omomania or delirium tremens it is a de parture from health. The diseased state of brain cell Inebriety spreads by the contagion of is manifest irritation, like St. Vitus's dance, the dancing mania, and other nervous affections It is not an entity which can be east off like a gall stone Yet it must be something superadded to the human frame, which makes people afflicted with it differ from others who are in good health and have never been inebriated What is that something? Where is its seat? Ine briety has its origin in vice, and its sent is the brain

chemical change in the agent producing it drunken man loses self respect while under the influence of alcohol and its allies. Amyl compounds produce these changes more quickly than ethylic The man Conscience loses its power surrenders his will, or becomes the victim of delu sions which enslave him as long as the influence lasts As the sense of sight has its seat in some nerve cells, so faculties and mental powers are seated in other nerve cells If one set can be irretrievably damaged, so can the other As the sight cells are destroyed, producing blindness, so the seat of self respect, con science, courage, and other virtues becomes changed —the good is made vicious Though apparently there is no change, there is no longer a response, and as regards that particular faculty the inebriate is as a White atrophy of the optic nerve does not occur till late in life, so few children are born with this inherited tendency So formerly intemper ance was uncommon in early years, and alcoholic heredity was unusual Of recent times, however, there has been increased facilities for the young to obtain liquor unknown to their parents, and alcoholic heredity is therefore more common Breeders of cattle are more careful than human beings about the observance of healthful habits of life in parents have observed in some children born after parental addiction to drink a tendency to drunkenness easily provoked by small doses of an intoxicant dren of the same parentage, before the intemperate habit had begun, I have seen no such tendency

A dinner in connection with the Congress took place in the large Hall of the Westminster Town Hall in the evening, when some 280 ladies and gentlemen were assembled

The Congress closed on July 7, in an excursion to the Dalrymple Home, the largest mebriate asylum in England

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, Friday, September 24, 1887 THE PRESIDENT, CHARLES WARRINGTON EARLE, M D, IN THE CHAIR

(Concluded from page 59)

DR J C, Hoag gave the following history of case of PLACENTA PREVIA

case of placenta previa which I saw a few days ago in consultation I was called early in the morning, and on going to the patient found her in labor, the labor being a little premature by perhaps three or She had suffered repeatedly from severe four weeks loss of blood during the last three months time I saw her, the os was sufficiently dilated to admit one finger only, the periphery of the placenta could be felt throughout perhaps a fourth of its ex-She was having no particular hæmorrhage at that time, but had been flowing all night Every manifestation of action is attended by a deavored, a few hours later, to introduce a Barnes' The dilator, but fuled because the cervix was very unfavorably situated, being so far back in the sacrum that it was impossible to introduce even a small dila-I introduced a colpeurynter and left it for three or four hours, at which time the os was found to be pretty well dilated, and the remainder of the management was left to the other physician at his request, as he had not previously attended one of these cases By external examination, palpation and auscultation, I had no difficulty in finding the exact locality of the feet, the other physician introduced his hand, and with little effort was able to pass it into the uterus, he then seized the foot through the membranes, but had great difficulty in holding it was a good deal of difficulty in rupturing the mem-I tried it before the introduction of the colpeurynter, but gave it up and advised the physician to rupture the membranes wherever he could do He soon succeeded in doing this, and the case offered no difficulties afterwards There was very little loss of blood The patient was afterwards treated with two antiseptic douches per day, and has done very well since The child is living

Dr Merriman How much hemorrhage was there after you introduced the colpeurynter?

Dr Hoag Very little

DR EARLE Did she get an intrauterine douche immediately after the operation?

Dr Hoag Yes, immediately, before the colpeurynter was put in and after the extraction of the child, and she has had no temperature above 90°

Annual Meeting, Friday, October 22, 1887 THE PRESIDENT IN THE CHAIR

The following officers were elected for the year, 1887-1888, after the reports of the secretary, treasurer, and editor were accepted

President —Henry T Byford First Vice President - Philip Adolphus Second Vice President - Addison H Foster Secretary and Treasurer -Edward Warren Sawyer Editor - W W Jaggard THE PRESIDENT then delivered his

ANNUAL ADDRESS

The secretary and editor will narrate the extraordinary work accomplished by the Society, will tell of its fame in foreign lands and its value at home, and so nothing is left for me to do except to plunge I might refer to a case which I attended recently at once into the subject that I believe is of more imin which there was one point of interest, it was a portance, not to you as representative men in the

advance of obstetric practice, but through you, as teachers and members of a special society to the great mass of practitioners whom your words influence, than any other I mean the influence of the development of the germ theory on the practice of obstetrics The words of experience which comes from Fellows of this Society regarding laparotomies, Alexander's operations, and total extirpation of the uterus are most valuable to a few-possibly one in one hundred or one in one thousand, for not more than that number should do these operations, although more than that number may attempt them But the inculcation of the duty to practice aseptic obstetrics applies to nearly every practitioner, for out of the great multitude of doctors there are found very few who do not practice this art and science Not many months since, Mr Lawson Tait paid a visit to Professor Tarnier at La Maternité professor called the attention of Mr Tait to a linear chart on the wall of his room, showing the total death rate of women confined in that hospital from 1792 to 1886 This record is divided into three periods the first that of inaction, in which the mor tality was from 9 3 to 20 per cent, the second, the battle of hygiene against infection and contagion with a mortality of 23, and third, the victory of an- In another, with a mortality of 116 mothers, 13, or a tiseptics, with a mortality of less than 1 per cent, trifle over 10 per cent had died and in the Tarnier Pavilion, a little maternity constructed under his immediate direction, since June, aseptic obstetrics will save more lives than can be 1880, with 785 deliveries, not a death has taken place

In 1870 to 1872, the influence of microbes in the etiology of disease began to be noticed, and in 1878, Pasteur began his investigation, from which we commence data to prove what is now known as demonstrated in regard to germs Previous to this, however (1857), Tarmer demonstrated the contagiousness of puerperal fever by inoculation Mayerhofer (1870) viewed the micro organism in the putrid discharges of childbed women, and Orth, Klebs, Hiller, Koch, Rokitansky, and others were conducting their About 1880, Pasteur believes he saw the microbe of puerperal fever Condensed for

practical use, it has been demonstrated

crowded with organized microscopic beings They live and multiply at the expense of organized hours before an expected confinement the room may 3 Their penetration into tissues produces 4 The skin, respiratory and digestive passages furnish the channels into the body healthy tissue has never produced a microbe Any abrasion of tissue against which these microbes come makes it possible for them to enter the system 7 Unless germs are brought from without there can be no infection 8 Many things in regard to the virulence, nature, attenuation, age, and development are yet under consideration

The appliance of these principles, with many others undoubtedly, has given the victory to anti-septics in hospitals With a mortality of only onehalf per cent, but little more can be expected what can we say regarding the mortality in private practice? Is it necessary, is it expedient, is it pos- main, it is because the people are ignorant of what sible to apply antiseptic measures? I have already these surroundings produce, but the average obremarked that the returns from private practice are stetrician is not free from serious responsibility that

not in, they never will be, they never can be, and until it is understood that what is called by so many milk-leg is puerperal infection, that in many cases mastitis is puerperal infection, and that chills and perspiration and abdominal tenderness after confinement is not necessarily simply malaria or a mixture of typhoid and malaria, but in the main is puerperal infection—I say until these things are better understood, and the great mass of practitioners are willing to call things by their correct names, a truthful percentage of deaths from puerperal cases in private practice can never be known From time to time indirect and unexpected testimony comes to us in regard to mortality from puerperal disease in private A student of mine, now practising in Michigan, narrates to me that a neighboring practitioner has lost 12 in six months It has become a standard quotation in obstetric literature that many years ago a celebrated obstetrician with a purulent catarrh in four years and nine months had 95 cases of puerperal fever with 18 deaths

In one insurance company whose papers I have examined, 187 mothers of those applying for insurance had died, and 32 of these, more than 17 per cent, succumbed to some form of childbed disease

Reiterating again that the practice of clean or saved in any other department of medicine or surgery, what are some of the means which we can use in its practice in private families—in other words, how far can we apply what has been demonstrated as reducing the mortality in hospitals to our work in families? It is not necessary to speak of isolation, apartments in private dwellings are hardly ever so crowded with sick as to insist upon this We should, however, see to it that the air is pure, and if infectious diseases have taken place, take measures to destroy their germs With the possibility of saving a human life, or at least averting from two to six weeks of prostrating illness with its anxieties, expense, and uncertain prognosis, it is not asking too much if I That the air and the water of the earth is there is the least suspicion of a poisonous atmosphere that the room shall be disinfected be fumigated with sulphur, or the walls dampened with carbolized or mercurial water. In this way a great amount of accumulated dust is either rendered aseptic or thrown down upon the floor or carpet, which may also be disinfected It will, of course, be nearly impossible to dispense with curtains and carpets in private sick rooms, and in ordinary cases The furniture may be it will not be necessary washed, however, with carbolized water, and, above all, the bed and its bedding can be clean It may be suggested that such instructions are superfluous, and that the lying in bed is always aseptic In general practice this is not so, and many a practitioner But has confined a woman on a mattress previously used by a diphtheric or erysipelatous patient. In the

renders this practice so dangerous, not to say some-proper and efficient antiseptic precautions it will not times deadly

With the room and its appointments made pure, it will be well to see that the patient has some defi nite instructions as to her preparations As soon as it is known that her confinement is about to take place, I am in the habit of requiring her to take a warm bath, at the conclusion of which the lower part of her person is to be washed with carbolized It is also requested that one or two carbol ized vaginal injections shall be taken during the first

stage of her labor

I have no hesitation in saying that in my judgment, the occupant of many a lying in chamber has yielded up her life, and the earthly career of many a babe commenced without the love and tender care of a mother, through the filth and ignorance of the so called practical but untrained nurse The position of nurse is too easily acquired—a woman whose hus band has died, a woman whose husband is unfortun ate in business, a woman who desires a little ready money -without a particle of training-without the faintest conception of what infection means, is frequently and eagerly employed to fill these responsible positions. And these midwives caring for a child with purulent ophthalmia in one house, confining a woman in the next, and washing the external genitalia of a septic patient in the third, no wonder lying in patients die These uneducated people-nurses and midwives-go from place to place with their little hand bags containing dirty aprons, septic catheters and syringes, and with em anations from their persons of kerosene and valerian enter the lying in chamber to scatter germs of infec tion Some years ago, I was at a great loss to under stand the cause of a mild infection in the person of a wealthy Jewess confined in her beautiful home and surrounded with luxury, and where I had taken the utmost antiseptic precautions, the incautious remark of the nurse that the patient previously attended by her had a milk leg explained it fully If everybody is to nurse, we must insist that they subscribe to cer tain rules of cleanliness, and have some knowledge of the etiology of puerperal disease

Precautions to be Observed by the Doctor -To believe that he may carry the poison from one patient to another is his first great duty This acknowledged, he will take some kind of care, varying from a brief exposure in fresh air to complete antiseptic precau One of the most able and convincing argu ments ever set forth, and which accomplished a vast amount of good and saved many a mother's life, was the essay of our own countryman, Dr Oliver Wen dell Holmes As early as 1843, while the intellect of Semmelweiss on another continent was revolving the same subject, Dr Holmes established and set forth the following 1 Obstretricians should not take active part in autopsies 2 If so engaged he should before attending a case, and 3 The inexpediency of obstretricians attending cases of erysipelas and certain other diseases the use of disinfectants, the contagious principle can opening after the birth of the child

be necessary for us to remain in quarantine the only safety in addition to knowing the virulency of germs, is to be willing to disinfect one's person and know how to do it. If we appreciate a danger we will take care to avoid it. The time has not come when many of us can refuse to do general practice, to attend cases of scarlet fever and diphtherra, and open abscessess, etc But if we realize the fact that we have made ourselves partly or wholly septic, and desire and know how to make ourselves aseptic, we are undoubtedly in a safe position as regards our patients It is the carelessness and inactivity of which I complain It is futile to claim that absolute cleanliness is practiced in anywhere near a majority of cases, or that any attempt is made toward antisepsis It is done by a few but the great mass must still be brought up to it In 1875, Dr Foote, in a paper on puerperal peritonitis, read before the Illinois State Society, presented evidence something A doctor with a phlegmon on his finger attended a lady in confinement. She died in a few She was nursed by her husband, who soon after had erysipelas In other cases diphtheria was present in houses where confinement occurred, and puerperal peritonitis followed Another gentleman reports an epidemic in his county with 60 or 70 cases and yet nothing was suggested This is the period of maction with us We are theorizing in regard to The battle against them contagion and infection with cleanliness and antiseptics has not commenced

As late as 1881, one of the ablest obstretricians in our State wrote "If pains are frequent and regular and so efficient as to have dilated the os uteri to the size of a dollar, the attendant engages two fingers in its lumen and gently dilates it." The development of the germ theory has brought out the facts that such interference is not only unnecessary but is attended with danger of infection In the majority of cases it is not necessary nor good practice to dilate the os uteri artificially, indeed our instruction and practice should be to make very few vaginal examinations When the doctor enters the lying in chamber he should have the supreme knowledge that he is asep-He should freely use the hand brush with soap and water, and it is hardly necessary for him to make more than one or two examinations The finger should be lubricated with iodoform mixed with sweet oil or vaseline, or a sublimate solution Let as far possible the position of the child be made out by external examination In addition to the doctor's clothes and person being aseptic, there should be a full and complete conception of what autopsies and personal contact with scarlet fever, diphtheria, erysipelas, and suppurating surfaces will do The studies of the past few years have demonstrated this was suspected before its full significance was not Let the placenta be expressed, not followallow some hours to elapse, and change his garments ing perhaps all the details of Credé but with slight traction on the cord and little pressure from above It will not be necessary in a percentage of cases Since we now know that, by worth mentioning to pass the fingers into the vulvar in most cases be destroyed, it is probable that with ruptured perineum let it be closed at once, using all

antiseptic precautions the parts without laceration, or if the laceration is only very slight, wash out superficially with a little carbolic or sublimate and throw in 30 to 60 grains of ing fluid 10doform And if there is the least suspicion of a tainted atmosphere, if, notwithstanding your instruction everything external is unclean and sometimes filthy, see that there is no gaping of the vulvar orifice, and protect the parts by the application of a piece of lint, 6 by 4, saturated with some disinfectant, this to be changed as often as soiled

Attention to these four things will absolutely change the results in general obstretric practice i The antiseptic hand, 2 the clean patient, 3 few, if any, vaginal examinations, 4 antiseptic precautions to the lower part of the parturient canal Time will hardly permit me at this occasion to more than allude to antiseptic precaution to be taken in dangerous, difficult, and impossible labors If the forceps are used they should be thoroughly washed and brushed before introduction, and covered with vaseline and iodoform, a vaginal antiseptic douche should be given before and after the delivery of the child As to whether an intrauterine disinfecting douche should be given after forceps delivery is perhaps an open question, but after all operations where the hand has been introduced into the uterine cavity this should always be done If post-partum hæmorrhage take place, give a hot antiseptic douche rather than to introduce medicaments which may produce infection, and if from any cause dilators or a tampon or the colpeurynter are used, let them all be aseptic

There are a few things applicable to patient and nurse, and it appears to me it would be well to have something in the same line presented, and upon taking an obstetrical engagement hand a copy to

To the Patient —Let her understand that strict attention to instructions which you will give her will almost absolutely insure her against those complications which make the getting up so tedious You make the following suggestions The lying-in chamber should be in a room where no infectious diseases have been treated, and all bed clothing should be prepared by boiling in a given per cent of carbolized water Do not select a mattress which is filthy for fear that a better and cleaner one will be soiled by blood and other discharges during the con-Do not provide pieces of old comforters, Let all appliances for the lying in chamber be those local societies should treat with equal respect the the sanitary condition of which is problematical with the history of which you are familiar borrow syringe or bed-pan, and assure yourself that those you have are boiled or washed in hot water and thoroughly carbolized

To the Nurse -She must be a believer in cleanliness, and must recognize that the doctor is to be director of whatever is to be done No instruments, appliances, package of roots or herbs, or garments of any kind which have been used in other lying in chambers are to be taken to other patients clothes she wears are to be thoroughly washed in a lowing resolutions, presented by the Executive Comcarbolized or mercurial solution, and she is to ac knowledge that she believes in the use of the hand

If there are contusions of brush and soap She is to make no examinations in your absence, and never touch the female genital organs without cleansing her hands in some disinfect-If she has been in attendance at septic patients, she is to receive instructions from the attending physician as regards methods of personal disinfection

DOMESTIC CORRESPONDENCE

A QUESTION IN ETHICS

Dear Sir —A point in ethics How is the action in ethics of the Secretary of a State Medical Association in accord in ethics with the National Association, who, as a member of the Board of Censors of a District Medical Association, recommends an M D for membership in said District Association, when said Secretary knows the M D recommended, and elected on his recommendation, stands at that time suspended from the State Medical Association on charges preferred and sustained?

ENQUIRER

ANSWER We do not know any provision in the National Code of Ethics on which an answer to "Enquirer" could be based The Code of Ethics is designed to define clearly the relations and duties of individual members of the profession with each other, with their patients, and with the community at large But the mutual relations of organized medical societies, County, District, State and National, must be regulated by the constitutions and by-laws that they severally adopt For illustration by the constitution and by-laws of the American Medical Association, no member of the profession can be received as a member who is not in good standing in the local society where he resides if such a society exists, and if any member is regularly tried and suspended or expelled from the local Society of which he had been a member, his name is dropped from the roll of members of the National Association, and remains so as long as he continues suspended or excluded from his The by-laws of many of the State local society Medical Societies establish the same relation between the State and the County and District Societies of If the National and State their respective States Associations thus pay due respect to the judicial and ethical decisions of the more local societies, it would certainly appear highly proper and important that the Do not Judicial acts of the State and National organizations EDITOR]

NECROLOGY.

T R VARICK, M D

At a stated meeting of the New York County Med-The ical Association, held December 19, 1887, the folmittee, were unanimously adopted

WHEREAS, Dr Theodore Romeyn Varick, in obe-

usefulness, and

WHERLAS, We, as Fellows of the New York Co Medical Association, to whom he was endeared by many acts of friendship, desire, in appreciation of his admirable qualities, to pay a tribute to his mem-

Therefore be it

Resolved, That we have ever recognized in him a man of sterling integrity, generous impulses, and THE OFFICERS OF THE NEXT MEETING OF charitable deeds, one who by his achievements in surgery has advanced the knowledge of his art and added not a little to the glory of our common pro fession

Resolved, That we especially cherish his name for his self reliance and independence, his ethical consistency and his loyalty to science, his edifying re marks in debate, and his substantial contributions to medical literature

Resolved, That we offer to his family our sincere sympathy in their sudden bereavement, and trust that their sorrow, like ours, may be mellowed by the memory of a life well crowded by works, begun in conscientious endeavor and ended not without JOHN SHRADY, M D, Pres't benefit to humanity

BOOK REVIEWS.

A PRACTICAL TREATISE ON MATERIA MEDICA AND THERAPEUTICS By ROBERTS BARTHOLOW, M A, M D, etc Sixth edition, revised and enlarged 8vo, pp xxiv, 802 New York D Appleton & Chicago W T Keener Company 1887

Additions to the amount of almost one hundred pages have been made to this edition of Dr Bartho low's very popular book Some things that the read er would wish to refer to and learn more of are, however, not mentioned in this edition, e g, lanoline, ichthyol, salt water infusion, blood-injections. Among the additions we find descriptions of antifebrin, antipyrin, strophanthus, sparteine, and other recent The author has, almost to perfection, that impartial judgment and ability to weigh evidence that is most necessary for a writer on materia medica, and this is shown on every page of his book The very complete clinical index is one of the many excellent features of the book

600 MEDICAL DON'TS, or the Physician's Utility Enhanced By Ferd C Valentine, M D, Ex-Surgeon General Army of Honduras, etc, etc Sm 8vo, pp 144 New York G W Dillingham 1887

There is a wonderful amount of good advice in this little book, and it is given in such an easy and interesting way that it is much more likely to be re membered by the reader The book is written for the public in the interest of the physician other "don'ts" might be added Don't imagine that mercury can get into your bones, Don't imagine

dience to the mexorable destiny of our race, has on your face, Don't believe that growing plants paid the common debt of nature in the prime of his (except highly odorous ones) in a room are unwhole-It is rather surprising to note that the author says that "prescribing is the physician's avocation" If so, what is the physician's vocation?

ASSOCIATION ITEMS

THE ASSOCIATION

We learn that the committee of arrangements is organizing and preparing for a large meeting of the The work of the Asso-Association at Cincinnati ciation is now progressing so harmoniously that we can safely prophesy that the meeting will be a successful one in every way We append below a list of officers and the addresses of those with whom members are most likely to wish to correspond

GENERAL OFFICERS

President—A Y P Garnett, Washington, D C Vice Presidents-Duncan Eve, Nashville, Tenn, Darwin Colvin, Clyde, N Y, Charles J O'Hagan, Greenville, N C, A Stedman, cor 14th and Stout Sts, Denver, Col

Librarian-C H A Kleinschmidt, 3113 N St.

N W, Washington, D C

Permanent Secretary-W B Atkinson, 1400 Pine St , Philadelphia, Pa

Assistant Secretary-Joseph Ransohoff, Cincin-

natı, Ohio Treasurer—Richard J Dunglison, Lock Box 1274, Philadelphia, Pa

OFFICERS OF SECTIONS

Practical Medicine, Materia Medica and Physiology-Chairman, ---- , Secretary, N S Davis, Ir, 65 Randolph St, Chicago

Obstetrics and Diseases of Women-Chairman, Eli Van de Warker, 45 Montgomery St, Syracuse, NY, Secretary, EW Cushing, 1 Hotel Pelham,

Boston, Mass

Surgery and Anatomy-Chairman, Donald Mc-Lean, 72 Lafayette Ave, Detroit, Mich, Secretary, B A Watson, 124 York St, Jersey City, N J

State Medicine-Chairman, H B Baker, Lansing, Mich, Secretary, S T Armstrong, U S Marine Hospital Service

Ophthalmology, Otology and Laryngology-Chairman, F C Hotz, 181 Clark St, Chicago, Ill, Secretary, Edward Jackson, 215 S 17th St, Philadelphia

Diseases of Children-Chairman, F E Waxham, 3449 Indiana Ave, Chicago, Ill, Secretary, W B Lawrence, Batesville, Ark

Dental and Oral Surgery-Chairman, J Taft, Cincinnati, Ohio, Secretary, E S Talbot, 125 State St, Chicago, Ill

Medical Jurisprudence—Chairman, E M Reid, 243 N Fremont St, Baltimore, Md, Secretary, C B Bell, Suffolk, Mass

Dermatology and Syphilography—Chairman, L D Bulkley, 4 E 37th St, New York, N Y, Secretary, S F Dunlap, Danville, Ky

REPORT OF COMMITTEE ON PRIZE ESSAYS

DR W B ATKINSON, Secretary of American Medical Association

Dear Sir —The committee appointed at the last meeting of the Association, by the Chairman of the Section on Practical Medicine, Physiology and Therapeutics, to examine essays that had been offered in competition for honor prizes, wish to report that, while certain of the essays showed considerable research on the part of the authors, no award was made, as it was thought that they did not fully meet the standard that should be required

Respectfully submitted

H A Johnson, N S DAVIS, JR,

E F INGALS

ROLL OF MEMBERS-OMISSIONS AND CORREC-TIONS - The name of Leslie E Tefft, M D, of Elgin, Ill, should have been added to the roll of permanent members published in The Journal, of December 31, 1887, and the following corrections in regard to residences have been furnished to us W L Downey, Vernon, Ill, should read Wenona, Ill, W G Putney, Streator, Ill, should be Prairie Center, Ill, A Wetmore, Monroe, Ill, should be Waterloo, Monroe Co, Ill, and the name of Albert Wing should be Elbert Wing

MISCELLANEOUS.

DR WILLIAM B WILSON, of Flora, Ill, a well known practitioner, died on January 19th He was graduated from the University of the City of New York in 1852

GUSTAV BERNUTZ, the distinguished French gynecologist, died at Sedan in December from chronic heart disease, the re sult of rheumatism He left some valuable lectures in manu script form, which will be soon published

PROPOSED OPIUM LEGISLATION -Secretary Fairchild has prepared a letter to Speaker Carlisle, showing the necessity for additional legislation to prevent the smuggling of opium, and recommending either a reduction of the duty on that commod ity or its restriction altogether

SCHOOL HYGIENE —MM F Dubrisay and P Yvon have just produced a work under the title of Manuel d'Hygiene Sco laire, in which all necessary information is given on the situation and arrangement of schools, the personal hygiene of school children, the prophylactic treatment of contagious or other dis eases, the organization of dispensaries

LECTURES ON INEBRIETY -The President of the English Society for the Study of Inebriety, Dr Norman Kerr, is to give the first course of medical lectures on the Disease of In ebriety and its treatment, in the hall of the London Medical So ciety, beginning Jan 12, 1888 Dr T D Crothers, of Hartford, Conn, has been invited to deliver two lectures on the same topic, before the Albany Medical College, Jan 24 and 25, 1888 These will be the first medical lectures on inebriety, formally presented to Medical Societies of Medical Colleges, and will doubtless attract much attention

DR WESLEY M CARPENTER, of New York, was found dead in his bed on the morning of January 7 He was born in 1839, and was graduated from the College of Physicians and Surgeons of New York in 1863 Since 1872 he was connected with the Medical Record, and was one of the best medical journalists that this country has produced His pleasant face was familiar to the members of every large medical organization in the country He was pecretary of the New York Patholog-

ical Society and of the Medical Society of the County of New York, Corresponding Secretary of the New York Academy of Medicine, Acting Secretary of the Practitioner's Society of New York, Clinical Professor of Medicine in the Medical Department of the University of New York, and Editor of the Quar terly Epitome of American Practical Medicine and Surgery

SPINAL CONCUSSION

Read in the Section on Medical Jurisprudence, at the Thirty Eighth Annual Mee'ing of the American Medical Asso ciation, June, 1887

BY N E BRILL, M D, OF NEW YORK

It is not surprising that actions involving the bas est characteristics of man's nature, the sordid ambition and desire for gain, should be accompanied by such disgraceful and wilful mendacity as is indulged in by both sides in those courts where proceedings for damages resulting from real or fictitious injuries received, occupy the attention of the judges and Wherever greed exists there will surely be found, as its accompaniment, other vices of as despicable a nature, and it is but too true that in this busy community, where the struggle for existence is the hottest and most butter, where success is due to ment and worth, and where industry and zeal alone tend to produce that condition of life which will permit the quiet and deserved indulgence of accumulated wealth, that there is found a large class whose chief desire is to live on the result of the exertions of others, and who never hesitate to utilize any means to acquire that desired end There is good reason, therefore, that suits for damages, brought deservedly and undeservedly, should be attended by those concomitants of avarice and greed, base deception and outrageous mendacity, and stand as a reproach to American medical jurisprudence

Viewing the subject from the position of an impartial observer, we must unfortunately admit, that mulcted, but that no condition in life, either lay or professional, is exempt from the base influences above spoken of The same infelicities may be found in the lawyers defending the companies, in the lawyers prosecuting a speculative claim, in the phy sicians giving their testimony in reference to the case, yea, even in the judges presiding, for it has been more than once the subject of remark that "even judges are corrupt," and hence not only is jus tice prostituted, but it is made the butt for ridicule others which I shall consider when I speak of testimony and its characters, which make a suit for damupon both the professions of law and medicine

It is only natural that, with increased facility for travel, with more speedy locomotives, making a journey between distant points less a task than formerly, railroads are patronized by a larger proportion of the With this increase in the riding popupopulation lation, with this higher development of speed and power, accidents are correspondingly more numerous and more destructive to life, limb and property

Where the injury received is one which is apparent to the restricted intelligence of the average juryman, there is usually no contention, but the companies occasionally settle to the satisfaction of themselves and of the injured, but where the evidences of disease and injury are masked, where no gross anatomical changes can be demonstrated, such as in that form of spinal affection due to concussion, then the contest begins with all the ardor and fervor of That the companies ought not be entirely blamed we may well understand when we reflect that in this disease the most prominent indications of a disturbed nutritive disturbance are evidenced only by subjective symptoms, too well conned and learned by simulators, who not infrequently do nothing but ride in cars in the hope that an accident may furnish them with the cause of applying their illicit knowledge to a pecuniary gain

In speaking of the effects of railway accidents on the central nervous system, we must regard first of all the nature of the person injured It is an undoubted fact, and one which is supported by the experience of all neurologists qualified to give an authoritative opinion, that persons with a neuropathic tendency have, after such accidents, developed functional nervous disorders, eg, hysteria, and that others with a hereditary history of nervous diseases not only is deception practiced by the companies have been likewise affected. Others with incipient nervous disease, which might have taken years to develop into its complete form, have after such accidents been seized with the violence of the disease in full development and soon succumbed it becomes necessary to bring out in all such cases the ancestral history, as well as the history of the patient himself, and though he be burdened by a neuropathic taint, though he be suffering from an acquired but incipient disease, the damages should be awarded just the same as if he had had a perfectly In addition to these causes, there are healthy ancestry, or if he himself had been possessed of all the vigor and strength accompanying the perfection of physical health, for we must be ages resulting from injuries a farce, and brings odium honest enough to say that were it not for the accident the claimant would still be in the necessary mental and physical condition fit to meet with the obstacles which must be overcome to make a living, and which could not be accomplished under circumstances entailing suffering and discomfort

While there is no reason that railroad accidents should not produce or provoke tabes dorsalis, such an occurrence is not yet proven But it is to be regarded as established that external injuries may restart an arrested or cured ataxia and aggravate an existing one 1

The effects of injury by railway accidents are various, and may be divided into two classes first class will comprise all the cases where the in jury is demonstrable both by its objective signs and by those subjective symptoms which we would expect to be present from an accurate knowledge of inches in the upper lumbar region where it was soft the physiology of the nervous system class will include all those cases which, from their very nature are unattended by any demonstrable signs, and which the neurologist alone can believe to be present by judging the subjective symptoms enumerated by the sufferer It is this class of cases to which the courts are most frequently introduced, and which are most frequently simulated by individ uals impelled by speculative rogues and shysters to a railroad should be held responsible where an accibase action for damages, and by whom even physicians are so liable to be deceived

It is my purpose in this paper to restrict myself chiefly to the consideration of this class, merely introducing certain other forms as subsidiary, and to utilize the latter wherever they may throw light upon and assist to a more accurate knowledge of the former, and be serviceable in deducing legal conclusions

That the consideration of even this restricted class of cases is one not unattended by difficulties, we have alluded to when we hinted at the data upon which verdicts are based If we free ourselves from the burden which legal precedents establish in arriving at such contradictory conclusions, and keep in mind, notwithstanding the testimony only too frequently offered by railway doctors who, with the greatest equanimity and without any pangs of conscience, deny that any serious damage can possibly accrue from any concussion, and who even throw aside all the most tangible and direct evidence of injury, that some of the most serious forms of central nervous disease, such as tumors, hæmorrhage of the spinal cord, and myelitis, do incontestably result, and if we weigh the evidence offered by both sides, reflecting that partisan spirit occasionally, if not frequently, leads to exaggerated statements, I think we may arrive at an honest and just conclusion, and one which the data of science will verify

This brings us then to the consideration of the pathological effects of concussion on the central

Unfortunately we labor under the disadvantage of coming to any conclusion as to the pathology of this class of affections, by the fact that the literature on Reports of cases with the subject is very limited autopsies (for it is only by post mortem evidence that the nature of disease can be determined), are very few, in fact, I have been able to find but three

One, a case reported by Sharkey, of a woman felled by a falling house, but who showed signs of a congenital defective development, such as partial paralysis and atrophy of right leg and arm, without loss of sensation, but with some contraction of the flexors of the arm, with exaggerated patellar and plantar reflexes, but no ankle clonus

There were no evidences of gross injury to any of the structures containing the brain and spinal cord, or of the tissues supporting the spinal column The congenital defect showed itself in an asymmetry of the brain, the left hemisphere being smaller than the right, and in a corresponding sclerosis of the right lateral column of the cord half the cord was normally firm except two or three The second and slightly wrinkled transversely The upper half, though not pathologically softened, was not so firm as the lower lumbar region In several places the right anterior cornu looked smaller than the left" Sharkey considers the autopsy to have yielded negative results, and attributes the softening in the lumbar region to post mortem changes

The interesting legal question arises as to how far dent, occurring through carelessness of their employes, produced symptoms of disease in a congenitally deformed individual This question was prompted by the case above alluded to, reported by Shar-In this case the neurologist is able to perceive that new damage was done, and what signs of defective development were original, since the examination of the spinal cord demonstrated the original abnormality and the acquired defect

A well known case described by Leyden, of spinal concussion due to a railway accident, in which the patient's symptoms for a time were but trifling, and he, not improving and becoming unable to work, was mistaken for a simulator, and finally, after many years, severe symptoms developed and resulted in The history of this case showed with precision the development of the morbid process and its connection with the original injuries, and the autopsy demonstrated a picture which was essentially dependent on a traumatic origin, viz a chronic inflammation (caseous) of the meninges, forming a peripachymeningeal tumor

A third case is found in the coroner's report of the accident at Wurzburg, where a man of 23 died three and one-half days after the accident, with symptoms of coma and dyspnæa, and chyle in urine topsy showed innumerable small punctiform hæmorrhages in the brain substance, about i cm in diameter The skull and spinal column were intact The patient, after the accident, developed symptoms and signs which could not be attributed to the original abnormality, and which Sharkey rightly considers to be due to the concussion accident For this further disability, restricting still more the field of usefulness of the individual, I am of the opinion that a compensatory remuneration should be given, which would be both equity and justice

In view of the light which subsequent investiga

Brain, Vol vii, p 99, 1885

morbid anatomy of the cord after these accidents, I do not think that anybody now accepts his expla That there is no inflam nation as at all plausible mation of the spinal membranes has been demon strated on innumerable occasions, both clinically and on post mortem examination Indeed, his term spinal meningitis is inaccurate, as there has never been demonstrated any inflammation about the spinal the hysterical mental state, be abandoned cord It seems that the molecular disturbance which the cord undergoes from the sudden shock is one in common to this affection

Erichsen's description would at the present time cause his cases to fall under the category of spinal we are deeply under obligations to him for his expo sition of a subject which had been veiled in incerti tude and doubt, still we ought not, on that account, accept as dogma what has not been satisfactorily

Berlin's compares the effect of concussion on the as a result of which the retina developed a slightly diminished acuteness of central vision and presented, 'hysteria on ophthalmoscopic examination, a clouded and Both of these conditions disap dulled appearance

peared after a short time

Thomsen and Oppenheimer together studied the disturbing effects of railway accidents on sensibility and on the special senses, and Putnam, of Boston, records a few cases where concussions have produced, in male subjects, impairment of the sensibil ity, general and special, of one side of the body, and sometimes in a slighter degree, of the other side In three of the latter's cases (five are recorded), no claims for damages were instituted, and hence there was no ground for simulation or deceit, so that Put The latter also sup nam's findings are trustworthy ports the views of Oppenheim and Thomsen with regard to the significance of hemi anæsthesia, which does not necessarily justify the diagnosis of hyste Charcot, in a recent contribution to the subject, characterizes the mental and sensory disturb ances of "railway spine" as hysterical, and contradicts this important conclusion of Oppenheim and Thomthat in a certain class of cases irreparable damage to the nervous system is done, by the very easy process of ignoring their strongest argument, so that one feels tempted to compare his procedure heim and Thomsen regard such symptoms as optic æsthetic over forehead to eyebrows nerve atrophy, paralysis of certain pupillary movements, and epileptic attacks, as definite symptoms which neither simulation nor hysteria can mistake, and which indicate organic change of some kind Certainly their conclusions are in accord with the

It is high time that neurologists, with all due deference to their scientific acumen and ability, should volving the ultimate anatomical elements, the nerve abandon the custom of exhibiting their ignorance by cells, interfering with their nutrition and their vital ascribing all phenomena which they cannot explain ity, and thus producing the features which are so on an objective basis, to that vague disease, hysteria This has its analogue in the practice of those physicians who call all, to them inexplicable phenomena of disease, malaria, and which is but a cover to hide Although there can be no doubt but that their inaccuracy, or but an expression of a want of

knowledge

Here is a symptom complex, indicating a disease which is allied to the neuroses, like hysteria, like spinal irritation, like epilepsy, but which differs from them in many particulars, the latter indicating inte-But because there is a similarity in gral changes central nervous system to that of a blow to the eye, the picture to these neuroses, there can be no justification in combining all the neuroses under the term Oppenheim considers this an important point that in his cases epilepsy in all its forms (the epileptic attack, petit mal, psychical equivalent), is a most conspicuous feature, while hysterical convulsions of the form which Charcot describes with "grands movements arc de circlé, etc ," are subordinate features, and he repeats the statement that anesthesia, with the envolvement of the sensory functions, is not characteristic of hysteria

Oppenheimer⁷ reports the following

Thrown from Case I—C B, æt 28, fireman Struck head on pave horse attached to engine ment and cut a gash over right eye and wounded Unconscious Subsequently, scintillations and convulsive seizures In attacks tore about, lost consciousness for some moments, at others suddenly jumping up and forcibly attempted to escape, and restrained only with difficulty These attacks preceded by pain in scar and scintillations in right eye After attacks severe right sided headache for half The patient himself observed that the skin in When washing he nocertain spots is insensible ticed, on wetting his hair, that he could not feel on anterior half of the scalp Sexual power gone disturbance of intelligence or memory

Examination of sensation shows anterior half of to that indulged in by "medical attorneys" Oppen- head anæmic to tactile and pain irritation, also an-Lower third of right forearm and hand insensible Muscular sense of right upper extremity much injured

jective symptoms and objective signs taken most'y from his summary

tions have thrown upon Erichsen's explanation of the current views of all neurologists except M Charcot They are therefore justified in protesting against M Charcot assuming that the usual capricious change of signs found in female hysteria is replaced by melancholia and depression in male hysteria, and thus justify the diagnosis of "railway spine" as a hysteria They rightly argue that the sufficiently vague picture of hysteria will dissolve entirely if its best criterion,

³ Wandeversammlung der Sudwestdeutchen Neurologen und Ir renarzte in Baden Baden am 21 u 22 Mai 1881 4 The Medico Legal Significance of Hemi Auæsthesia after Con

eussion Accidents

3 A propos de six cas d'hystérie chez l homme Leçons etc
grès Médical 1885 No 18

The wisest are not proof against error and a mere error especially where it is honestly admitted can constitute no reproach to the fame of M Charcot. But his unfortunate experience in the past should teach him the need of caution and that it is unwise to categorically formulate. He had the misfortune to discover lateral sclerosis in a woman with spastic contracture which he regarded as hysterical. It is true that rather than abandon his diagnosis. M Charcot resolved to sacrifice every definition of hysteria but the neurological world at large were not prepared to join in the sacrifice.

Arch fur Psychiatric Bd xvi 3 5 743 1885. The following two cases are selected from the ten recovered and the enumeration of subjective symptoms and objective signs taken most's from his summary.

lower extremity diminished sensibility in lower portion of thighs and feet. Also disturbed muscular sense in feet Absent, sole reflex Vision scintillations, concecutive narrowing of visual field for cuted with slight force white and colors on both sides

Westphal's Case 8—The patient whom I present to you (Berliner Gesellschaft fur Psychiatrie und Nervenki ankheiten) was perfectly well up to January 14, 1886, when he was the victim of a railway accident He was the baggage master in a freight train, and suddenly felt a concussion, followed by another, was hurled forward and fell unconscious to the floor Be came conscious in five or six minutes When removed from the wreck he showed no external injury, feeling of distrust. Their fears are undefined ("I but was immediately very much excited restless and broken by wild dreams he complained of pains in the head and back, he had paræsthesiæ of different kinds, sensation of deaf When examined the psychical anomalies ness, etc and disturbances of sensation were predominant

Patient is fearful, ill tempered (vershieunt), and is troubled with hypochondriacal hallucinations (vorstedungen) Sleep is bad, even during the day he tinually complain of them to the physician is seized with intense fear, which at times has no defined motive, at others is called forth by the sound not be demonstrated any inordinate disturbance in of the locomotive of a train seen forms and was much worried thereby psychical anomalies of a hypochondriacal melancholic character are very constant. Of a very peculiar character are the anomalies of sensation, which are ever present and do not change in intensity and extent Sensation remains in only circumscribed portions of the surface of the body, viz in the region of the nasal orifices, on the lips, over the lower half of the sternum, over two symmetrical regions on the anterior surface of the forearm, over the most of the region between the left seventh and ninth cervical vertebræ on left side, over two symmetrical spots on the inner surface of the upper thigh, and finally, on the penis and scrotum While on these small regions of the skin tactile and painful irritations are well defined, and temperature sense is present, on all the rest of the surface of the body (including the mucous membranes) sensibility is entirely abolished to all irritations

The muscular sense is also not intact, still, its exact

extent has not been clearly determined

With disturbances of sensation are also disturbances of special sense the field of vision shows lim itation for white and the colors, smell and taste are almost entirely abolished, and acute hearing on both sides, especially left, diminished Ophthalmoscopic examination shows nothing abnormal Patient complains of photophobia and scintillations before the broken by gaps and was incorrect No signs of paralysis of the ocular muscles are eyes present

As far as the motility of the extremities is concerned the strength of the hands is very little, voluntary movements are accompanied by tremor, which

occasionally presents itself in rest

Patient walks carefully, with difficulty, and soon

When examined on his back, quite a stiffness tires in the joints is perceived Tendon reflexes are of the usual strength, the active movements are exe-

These are but two of ten recorded cases of Oppenheim, and are here utilized to bring more forcibly to your consideration the psychical and physical disturbances In all the cases recorded the chief psychical change is the emotion of fear, the patients are sad, have painful conceptions, shun society, are fond of isolation, are indisposed to speak, and when they do speak harp on their sufferings and their disease, are easily disposed to cry, and some have a morbid Sleep was feel as if I had committed a crime, and as if some Subsequently misfortune were going to happen to me," etc.)

> The most complain of insomnia and some of restless sleep disturbed by fearful dreams, in which the history of the accident plays the chief iôle psychical disturbances are hypochondriacal in character, and the patients exaggerate the slightest uncomfortable sensations, brood over them and con-

As far as the intelligence is concerned there could Occasionally he has any of these cases These persons are not psychi cally weak, but they are not able to undergo any continuous mental exertion All complain of weakness of the memory, but a more minute examination shows that their memory has not suffered essentially They can recall quite well the from its normal events of the far past, but, on the other hand, they forget commissions which have been recently intrusted to them, also names, residences, etc in one case was there conspicuous weakness of memory, in that events which ought to have definitely interested him were entirely obliterated from his memory

> All the patients report attacks of syncope quently there was but an evanescent vertigo with in distinct consciousness, at other times the attacks could not be differentiated from those of petit mal In one case there were distinct epileptic attacks, the patient fell suddenly to the ground with loss of consciousness, and lay motionless for many hours After these attacks there was a marked change for the worse in their general condition In the first case reported, attacks of complete loss of consciousness occurred, preceded by an hallucinatory condition of cloudiness, of dreaminess and of fear, called forth frequently by external causes-signal of the fire en-After these attacks the sensorial anæsthesia also deepened, and the memory of the occasion was

Subjective Signs - Patients complain of pressure in the head, more or less of headache and pain in the back of the neck, dull sensation in skin of scalp, also peculiar paræsthesiæ in the same place (as if worms were creeping under the skin and like sensations), feeling of giddiness, of drunkenness and ver-The vertigo is to a greater degree continuous, and increases occasionally so that the patients have to hold on to prevent themselves from falling

few cases there was obstinate vomiting

tinually raining finely

ances are almost unspoken of

back and loins, and indicate themselves by their difficulty in walking the truth of these sensations and a girdle pain was indicated

In five cases sexual power was entirely obliterated An almost constant indication of the disease was painful expression These sensations the disturbances of sensation in intensity and mode of distribution Usually there membranes The sole refleves may be entirely absent only confined to the skin and mucous surfaces, but cases thesia which is spoken of by French authors as its served characteristic form occurred in our observations but seldom, but, on the other hand, it was not uncommon that one half of the body suffered intensely while the other half but partially

A few times there was bilateral symmetrical anæs thesia, the anæsthesia being distributed to symmetri With a pecucal spots on both halves of the body har preference were the hairy scalp and the forehead to the eyebrows the seat of the disturbed sensation Again, there are greater or small regions over the extremities in which altered sensation was prominent The presence of entirely circumscribed spots of sen sation within an anæsthetic territory is remarkable In one case the fingers are sensitive, while the other parts of the upper extremities have no sensation In the lower extremities these exceptional spots are re stricted to the soles of the feet

The least constant in these cases is the disturbance of the so called muscular sense A remarkable phenomenon is the fact that in some cases the patients complained after one half to one hour of the pain produced by the prick of a pin to the anæsthic part

Sometimes functional disturbances are confined to an individual organ of special sense, at others to all of them Limitation of the visual field is the constant factor in the group of sensible sensory anomalies, still, there are cases in which, notwithstanding the disturbances of the functions of the other special sense organs, there is no marked alteration in excentric vision

As far as the results of the disturbances of sensation on other troubles are concerned, these are not, for the most part, material Delicate manipulations with the hand are hindered by the dulled sensibility, but usually only so little that the affected individuals can help themselves very well with the use of their The limitation of the excentric vision does not materially influence the determination of position not materially influence the determination of position in space. Hirschberg, though, calls attention to the

They complained of flashes before the eyes, or of fact that excentric vision is not entirely obliterated a cloudiness as if from smoke or as if it were con- in the apparently absent part of the visual field, else On their attempts to read the these patients could not determine their position in letters seem to dance and merge into one another, space. But Oppenheimio says that in a part of his at times the field of vision is darkened for a few cases excentric vision in the obliterated territory was seconds In one case there was the conspicuous entirely gone, in others the movements of large obphenomenon of vanthopsia which occasionally oc spects were certainly recognized, but that in his cases there was a good harmony, for the most part, be-Many complain of obstinate tinnitus aurium and tween the degree of visual field limitation and the of impaired hearing power. Smell and taste disturb. disturbance of the ability to determine the position in space, since the limitation of the visual field from All complain of pains and feeling of tension in the 30°-40° does not produce any prominent disturbances

Not infrequently are there skin territories which In manifest pain when disturbed Especially is this true a few instances there was a distinct girdle sensation, of the lower region of the back, if pressure on the spinous processes evoked much pain, a few cases manifested even on slight touch of the skin marked

Corresponding with the diminished sensation there present in the different cases the greatest differences is diminution of the reflexes of the skin and mucous is sensory anæsthesia, i e, dulness of sensation is not. Absence of corneal reflex was never found in these Tendon reflexes are either normally present or also to the organs of special sense. The hemianas are slightly exaggerated, their absence was not ob-

> There is a certain retardation and want of energy to muscular movements, although, on account of the attending pain, it is difficult to determine tempting to raise the leg from its position the patients double up with pain, press their hands over their hips, Almost typical is the position of the body in standing, walking, in sitting erect, and taking their Each patient endeavors to protect his vertebral column from every concussion, as a result of which he does not move the upper half of his body, arises by supporting himself with his hands and slowly draws himself up by their means They walk slowly, spread their legs apart, usually in walking they place their hands over the small of the back Swaying on closed eyes was not observed

A moderate degree of tremor is present the disturbance of motion has the form of a hemiparesis, and in these cases the anæsthesia has its chief seat in the paretic half of the body, but the hypoglossal and the facial regions are not involved

The bladder function is frequently disturbed, the urine only being passed after much pressure, in one case urmation could only take place in the sitting position, and one patient had to use the catheter

Constipation is a common complaint The foregoing is the common symptom picture The following are the differences from the stereotyped form One case presented disease of the optic nerve on ophthalmoscopic examination A definite atrophy of the optic nerve was found in another, right iridoplegia and inequality of the pupils in another

Signs of organic changes, differential diagnosis:

Indoplegia, optic nerve atrophy

Signs not found in the neuroses Abolition of sexual power, bladder paresis, girdle sensation

Oppenheim's conclusions are partly as follows

That sufferers from these accidents present devel oped disease symptoms which do not indicate any individual disease, and do not present many variations among themselves, notwithstanding they possess common features

psychosis and neurosis

That a great percentage of the cases show features indicating an insidious, continuous organic disease

of the nervous system

Since the result of these trials depends to a great part upon the evidence and testimony offered and given by men who are supposed to occupy the highest position in their professional sphere, who are credited with such an accurate and complete knowledge of the special subjects that their opinion is considered to be authoritative, it behooves us to consider whether the popular ideal of an expert is substantiated by the exhibitions of the majority of those who have appeared so frequently in the arena of litigation Have this majority the necessary qualifications of he whose education has been so conducted that he is training and education to give that evidence which in its effects may work incalculable damage by permitting the guilty to escape or bringing hardships to the innocent? As a silent, observant witness to numerous litigations, involving not only property but life, I can fairly say that it is exceptional to find one who has the necessary amount of knowledge, whose mind is sufficiently well educated to reason and to assimilate scientific truths, who has sufficient industry and energy to devote himself to almost incessant study, for the strides which science is taking are so great, that it requires all the time and attention of the scientific man to keep apace. But there are a few men who have these abilities, and who hesitate to enter courts to give the results of their study on account of the opprobrium which rests, and with What a justice, on experts and expert testimony benefit to mankind would it be if the courts could be cleansed from those experts who linger about the court-rooms or in neighboring grog shops¹¹ waiting for an anticipated case, who, having procured by some occult means political influence, receive the appointment of judges as commissioners de lunatico inquir-

Indeed and in fact the "political doctor" is as much to be feared as the "railroad doctor"

It is not without just cause that so much complaint has arisen over this class of testimony, and is due not only to the venality and bias of the expert and his ways, but to the ignorance of the lawyer The framing of hypothetical questions and the desire of lawyers to obtain answers to them independent of the relations of the assumed facts to the case under investigation, has wrought more harm than good, and tends to stultify the expert giving his testimony, the lawyers themselves being partly to blame for the effect produced on the public mind in their estimation of expert testimony

Another evil factor which operates is the system of badgering and attempting to confuse the witness which lawyers undertake in order to diminish the value of the expert's testimony by involving him in

a contradiction It is not my purpose to undervalue the system of cross examination Far from it! for I consider that an honest cross examination is the best means at our command by which we can test the ability and qualifications of the witness But I think That a part of these cases present a mixture of it high time that the arbitrary cross examination employed by lawyers should cease I have often listened to them attempting not to gain information, but simply to waste the time of the witness must consider that a physician's time is not only pecumarily valuable, but is often devoted to the saving of life,12 as well as to alleviating suffering) It is indeed unfortunate that one has no redress therefrom, yet we can console ourselves with the fact that the oftener this species of examination is indulged in, so much the oftener will the lawyer utilizing it find himself digging his own grave

We may ask ourselves What constitutes and what factors enter into the formation of an expert? This question can be answered from two aspects thoroughly well acquainted not only with all that is known of the special subject in his own country, but with the entire literature of the subject and, in addition, whose mind is so trained that his powers of observation and reasoning are such that he is able to form rational conclusions from observed cases, be they few or be they numerous For I am of the opinion that one case well conned and well observed is of more value than the careless and superficial examination of many Second, he may be designated an expert, whose experience has been so extensive in personal examination and reflection about cases that, with a relatively limited knowledge of the special literature, he is quite capable of giving a trustworthy The latter's powers of observation, however, must equal those of the former, and his mind must be equally as logical, otherwise all the expenence thus gained would be useless and valueless, and represent only barren isolated facts, from which there can be no deduction I think the expert belonging to the former class exceeds the one belonging to the latter in value, for he has not only an individual experience to guide him, but is thoroughly and perfectly acquainted with the experiences of all who by their recorded works are qualified to give authoritative opinions, whereas those of the second class have but an individual experience which, however great, cannot approach numerically that of the collected experiences of the rest of the scientific world

It would seem useless for me to emphasize the fact that the expert must, in addition to his educational It seems to me, qualities, be thoroughly honest though, that such an emphasis is necessary, for I have not infrequently heard the same expert give different answers to the same scientific fact on different occa-This is one of the reasons that I consider a rigid cross-examination as the best means to weed Fortunately, we have out the dross in our midst stenographic reports which accurately record the

¹² I have here in mind the cross examination of one of our most learned specialists, who was assured that he might leave in time to perform an operation which held in the balance life and death, and was detained by utterly useless questioning for 1½ hour beyond the agreed

have lawyers who know how to utilize such reports It is thus that cross examination not only reveals the status of the expert as to knowledge, 'but as to mo rality For is not the inference deduced from hearing an affirmative and subsequently, on another occa sion, a negative of the same scientific fact, according as such an expert (1) is testifying for one or the other side by whom he is engaged, sufficient to stamp him as dishonest and purchasable?

I would venture to say that, could we rely on the morality of experts, we would not find so many ar rayed against each other, for, were all actuated by the desire that truth should prevail and with no re gard for the condition of their pockets, there would be in the great majority of litigations but one ex-How can a fact be anything else pressed opinion than a fact, and how can the significance of a certain regular combination of signs or symptoms be consid ered in any other than their true significance? There may be honest differences of opinion in reference to the application of solitary facts or the significance of individual criteria, but there can be otherwise no honest cause for arriving at contradictory conclu Even in this connection there is more or less cant connected with the expression "honest differ ences of opinion" I do not think I need hesitate to say that the so called "honest difference of opinion" is in nine cases out of ten due to absolute ignorance of the subject on the part of witnesses and that this too frequently cited phrase is but one of the means by which astute, if not thoroughly honest lawyers try to cover and conceal the ignorance of their expert

Let the expert ever remember that his claim as such stamps him as a public man, whose actions are always viewed with microscopical exactness, and whose weaknesses are ever ready to be seized upon and magnified by a zealous and watchful public he pay attention to this it will not be long before he will give up that permicious habit of arguing the case, and confine himself strictly to his proper position the adviser of the court, counsel and jury aware that an evil jealousy exists among this class of witnesses, and that they, by having become em bittered by the greater success of some of their col leagues, have been led to step across the bounds of professional conduct, which should be an open, hon est expression of opinion, to one of mean, small and contemptible inuendo, which by its hidden sting is calculated to rob the testimony of the opposing witness of its force These men have become too cow ardly to openly attack their opponent with the weap ons of knowledge, or enter the lists in a fair contest of condition and intelligence, but must assail their antagonist with the meanest aspersions has passed when it is considered a reproach and degradation for a man who has been honestly en gaged in a study of comparative anatomy, and has utilized all the means at the control of science to become thoroughly acquainted with the subject, and who, having succeeded in this most laudable object, turns his attention to the instruction of others, to receive the application of the term "horse doctor," Read before the Society of Medical Jurisprudence and State Medi which was once suggested by an envious expert to

statements of medical experts, and fortunately we the attorney engaged in cross examining an opposing witness in a most noted recent trial Let the expert be perfectly fair and stand only in the position of one who is citing facts and elucidating truths which shall enlighten the court and jury, and assist in bringing the latter to an honest verdict. The jury are cer tainly intelligent enough to immediately perceive the expert physician attorney, and to reason that he I think it was chiefly this habit is a biased partisan of arguing the case which was indulged in by the expert witness for a large railroad corporation in a recent trial in New York, which induced the jury to give such an exceptionally large amount of damages, although to my mind the case was a sham one, and the railroad unjustly mulcted The following was a portion of the expert's testimony "

> O Will you be kind enough to tell the jury what is known as spinal concussion, in your opinion?

> A That is a term, spinal concussion or railway spine, or nervous shock due to railroad accidents, which has become very fashionable in the last two or three years, it was first discovered by Mr Erichsen, an English surgeon, and has been spoken of by several of the English authorities I look upon it as a very dangerous term, because it opens the door to unprincipled persons, who make use of it, when there are no nervous symptoms, to prosecute corporations

> Dr Spitzka, i in commenting on this testimony, "It is remarkable that the dangers of such an an answer to the defendant were not appreciated There is no jury of average intelligence that could not detect the bias of the witness giving it, and who would not naturally judge from the methods to the justice of the cause in whose interests they were em-But in this case it seems that the witness ployed was put on the stand to argue the case, for the counsel calling him followed up the above cited with the following

> Q Have you read Erichsen's work on nervous diseases?

A I have, sir

Q What is your judgment about that book?

A I think it is a very dangerous book 16

Q A dangerous book?

A Yes, sir, because it prevents scientific truth "If authorities are to be pronounced misleading and dangerous merely because they inculcate teachings which happen to support 'the other side' in a litigation, we may as well abolish them all"

Testimony like this is not calculated to strengthen the opinion of the public in the integrity of character of the expert, nor to produce a feeling of conviction as to the importance of expert testimony Indeed, the people have just cause to complain and have firmly expressed their convictions as to the unreliability and unimportance of this testimony

Is there not some cure? Assuredly, yes, and it

¹¹ Supreme Court County of Kings John I Harrold against the New York Elevated Company Case on Appeal 1880 Ref Proceedings of the Society of Medical Jurisprudence and State Medicine

is to be found in the very weapon in the hands of sents some 5 to 10 millimetres of clear space above the attorney cross examination It does not require an extended course of searching to elicit the incapability of an ignorant witness, nor to impeach his veracity where he has made his pecuniary aims the chief standard of his testimony I can advisedly state that a rigid cross examination by a competent less, but not invariably so But from this scarcely lawyer is the best means to either substantiate the position of the educated and scientific witness, as it is to discover and reveal his ignorance, his want of knowledge of scientific facts, and his character

It is useless for me, in such a paper, to enter more fully into the discussions of the means suggested to strengthen the position and importance of expert suggestions are inapplicable in the present state of a Republican government, where politics and political persuasion and influence are the most important factors in selections to official positions Hence the practice of Continental governments in appointing those men who, by their work, have advanced themselves to the highest pinnacle of knowledge in their special subjects, to the position of expert adviser to the court, beneficial as it is abroad, would not be accompanied by the same felicitous results in this country

HYPERTROPHY OF THE PHARYNGEAL TONSIL (Adenoid Vegetations of the Vault of the Pharynx) BY H GRADLE, MD,

OF CHICAGO

The frequency with which children are allowed to suffer for years, without recognition of the trouble, from blockage of the naso-pharyngeal space, seems to the writer sufficient excuse for presenting this article Admitting that these notes are but the confirmation of the work of others and do not claim to be an extension of our knowledge, it still seems desirable to me that this affection should be brought more to the notice of the profession at large, and not remain unknown outside the ranks of rhinologists

Most of the standard works on medicine scarcely mention this disease, if they refer to it at all, and even in the latest edition of Gray's Anatomy the existence of a normal pharyngeal tonsil is simply ad-As a matter of fact, mitted in one short sentence it is my luck quite frequently to see children whose nightly rest has been constantly disturbed, whose hearing has been imperiled or damaged, and whose growth even has been stunted by an easily remediable anomaly that had been overlooked or ignored respiration, especially of the expiration in the case for years by the family physician

The adenoid lymphatic tissue which underlies the mucous membrane of the pharynx is collected in a larger mass at the roof of the pharyngeal vault above and behind the posterior choanæ forming the pharyngeal, or Luischka's tonsil On its pharyngeal surface this organ is raised into ridges running in a sagittal direction, which ridges atrophy gradually after the age of puberty is passed, at least in most persons Normally the rhinoscopic image of the adult pre- Rachentonsille 1886 This tonsil is very frequently hypertrophied

the upper margin of the posterior choanæ not filled by the glandular mass Not rarely, however, the tonsil is enlarged sufficiently to make the roof of the pharyngeal vault flush with the border of the choanæ Such minor degrees of hypertrophy are often harmmorbid enlargement there occur all gradations, up to a tumor filling the entire pharyngeal space down to the level of the soft palate

In youth the enlarged tonsil is always lobulated The hypertrophy involves not only the body of the tonsil but also the ridges, giving the mass a coxcomb shape with irregular fringes and polypoid promi-It may be sufficient to state that all such nences If the tumor be allowed to remain beyond the age of puberty it acquires gradually a more regular outline by reason of the atrophy of these fringes and projections The more lobulated and fringed such a tumor, the greater is usually its vascularity and the softer its consistency, which makes it more difficult to grasp this soft movable mass with any instrument than the harder tumors of more regular The rarity of extensive hypertrophy of this tonsil in adult life renders it likely that the enlargement gives way to atrophy after the period of growth

The disease is much more common than is ordinarily supposed More than one-fifth of the children brought to me for ear disease suffer from this affec-In adult life, however, the predisposing conditions of ear disease multiply in number, so that the frequency of pharyngeal vegetations is considerably

less in adult aural patients

The causes leading to this enlargement are not vet evident It is often seen in scrofulous children, but my experience inclines me to think that it is more commonly the cause than the result of the condition known as scrofulous diathesis Such at least is the conclusion suggested by the improvement in general health after operative removal of the en-The query whether the larged pharyngeal tonsil tubercle bacıllus might be the cause of this disease, has been answered in the negative by the researches of Trautmann 1

There is evidently some irritative process favored by certain climatic influences which leads to the enlargement of the pharyngeal tonsil and very often also of the oral tonsils, and of separate lymphatic follicles in one and the same individual Nasal, or pharyngeal catarrh, may complicate the condition but it can occur without any evidences of inflammation of the mucous membrane

The direct symptoms are those of impeded nasal of softer tumors, which act like a valve The interference with the movement of air through the nose depends on the size of the swelling and on its vascularity Since the enlarged pharyngeal tonsil is capable of holding a variable amount of blood, like the entire mucous and submucous lining of the nose, any acute catarrh, or even the recumbent position, will cause it Hence the annoyance is most marked in to swell bed The children breathe with their mouths open and

usually snore when asleep The voice has a charac teristic "dead" timbre, there is no nasal resonance catarrh, the final n sounds like d, the m like b speech is so characteristic in well marked cases, that it enables the expert to make a diagnosis at once The enlarged tonsil often gives rise to venous conges tion in adjoining regions. Not rarely the eye lids and lips of such little patients are swollen and show Quite commonly the cavernous tissue of the nose is distended and adds its obstructive in influence to hinder still more the nasal respiration Trautmann claimed that the congestions were due to pressure of the enlarged gland upon the pharyngeal veins. But his own plates show the existence of such extensive venous anastomoses that this mechanical explanation seems to me insufficient Possibly the venous distension may be the result of augmented ve nous pressure during the impeded expiration Possibly nervous influences may account for the relaxation of collateral veins Trautmann also attributed the fre quent enlargement of the oral tonsils accompanying adenoid vegetations to this venous stasis, and claimed that the hypertrophy of the oral tonsils often recedes after extirpation of the pharyngeal gland This latter statement I cannot corroborate from my own expe

Reflex symptoms often accompany this affection The children may complain of frequent dull head ache, mainly in the occipital region, which does not return after the operation Sleep is often interrupted by sudden starts or persistent restlessness, probably due to harrassing dreams or nightmare A large number of my patients had vesical incontinence and soiled the bed every night. But since this annoyance did not disappear within the first few weeks after the operation I cannot claim with any positive ness that it was caused by the nervous irritation due to the enlarged tonsil, although its frequency renders a causative relation probable Occasionally a persistent cough was observed, like that of a mild middle ear degree of bronchitis, which ceased soon after the Quite a number of my patients were puny and scrofulous children of retarded growth and impaired vigor, though not considered really sick by their parents, merely delicate Since in some eight or ten of such cases a decided improvement occurred in the growth and vigor and general health of the children after the operation, I cannot but conclude that the tumor in the naso pharynx was the cause of their delicate health

hypertrophied pharyngeal tonsil is the ear are probably very few cases of extensive enlarge. in the direction of the cutting edge by disease of the middle ear simply impaired hearing without any active symptoms that so easily elude the grasp referable to the ear, and without any evidence of im

a few inflations of the ear hastens the restoration of But graver and more acute complications Similar as in the obstruction due to intense nasal also occur in the form of either suppuration or protracted catarrh of the middle ear These secondary affections once started are now to a certain extent independent of their original cause They require treatment of their own and can mostly be cured without removal of the enlarged tonsil, but are very apt to relapse, until the predisposing condition is obviated Fortunately the ear complications are as a rule amenable to treatment, though a long neglected catarrh of the middle ear may lead to permanent lesions

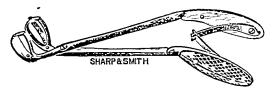

> The diagnosis of hypertrophy of the pharyngeal tonsil is suggested whenever a child presents more or less persistent obstruction of the nose, a dead timbre of the voice and occasional nasal hæmorrhages (although the latter have been rare in my experience) It should be thought of in every case of infantile ear disease If feasible the diagnosis is made absolute by the use of the rhinoscopic mirror But the mirror can only rarely be successfully used in children of less than 8 or 10 years of age In such unsuccessful cases the diagnosis depends upon the use of the finger The curved index finger introduced through the mouth behind and above the soft palate, detects a soft, flabby mass filling the naso pharynx, instead of the smooth wall of the normal space The examina tion is very unpleasant, and in pronounced cases is really unnecessary

No successful treatment has yet been devised except operative procedures, but the results of thorough operations are all that can be desired While nitrate of silver, in the form of dilute spray, may relieve the symptoms if aggravated by catarrh, it cannot cause absorption of the enlargement Cauterization with the galvano cautery is more efficacious, especially if we use a broad platinum blade, like a gouge, and thus remove fragments But this procedure is quitepainful and occasionally leads to suppuration of the With the ring shaped knife, originally used by Meyer, and passed through the nose, I have had but little experience It has seemed to me more unpleasant to patients than instruments introduced through the mouth The artificial nail, or nail shaped curette, fastened to the finger, I have never used I doubt whether the finger can find enough space for movement to do thorough work, and I do know from experience that the insertion of the finger is more disagreeable than that of any instrument My largest experience has been with ring shaped curettes, bent The organ which is principally imperiled by the at not quite a right angle, the ring being in the sag-There gital plane, which are rotated and pressed laterally ment which are not complicated some time or other ments are quite efficient, but must be inserted a num-Not rarely, there is ber of times in order to cut off all the projections

Since the appearance of Trautmann's work, I have plication of the tympanum beyond retraction of the mainly employed his curette, with fair satisfaction This trouble is probably due to dimin- It is the form of a round sharp spoon, 11, 13, or 15 ished patency of the Eustachian tube on account of millimetres in diameter, the shank of which is bent congestive swelling of the mucous membrane Be- at an angle of 150° about 3½ centimetres from its youd the removal of the enlarged gland there is end. The patient's head being suitably held, the scarcely any treatment required for the ear, although spoon is introduced behind the palate and forced upward along the posterior edge of the vomer, its cutting edge, being of course, directed towards the rear It is then pushed like a gouge backwards and downwards, and on withdrawal a fragment of the gland will be found in its concavity. It is at once reinserted a little more to one or the other side, and used again until the space feels clear as far as can be judged by sounding with the curette. If any remnants are left the operation is repeated after the traumatic congestion has passed off, that is, some five days later

All operations with curettes are followed by abun dant hæmorrhage, although this has never been alarm ing in my experience, in about 75 operations can always be checked by gargling with ice water, and will generally cease spontaneously inside of some five or eight minutes The operation is moderately As I have learned from older children and adults, cocaine does not relieve the pain materially, but swabbing the pharynx up to the vault with a 10 per cent solution of cocaine lessens the discomfort and retching produced by the instrument never yet used an anæsthetic, having always been able to persuade the children to submit, since the pain is of very short duration Hopmann, however, has reported 69 operations on anæsthetized children, without accident The entrance of blood into the laryny was prevented by not carrying the anæsthesia A drawback to all curette operations is the difficulty of finishing the operation in one sitting on account of the speedily exhausted patience of the sub-Sometimes four or five sittings are required to clear the naso-pharyngeal space

The operation has become much more elegant in my hands since I have had a pair of cutting forceps constructed on the principle employed by Loewenberg. This author's gouge forceps are so clumsy as to frighten patients, while the cutting end is too small to grasp much. Accordingly I have had a forceps constructed of a stout pair of scissor blades, the handles of which, about 15 centimetres long, are suitably bent so as not to obstruct the view. The

cutting end is a hollow triangle, base upwards, 17 millimetres high and 13 mm wide, which arises 3 cm from the scissor screw, sloping upwards and The cutting edge is the upper slightly backwards base which is slightly curved and slopes backwards so as to conform with the roof of the pharynx Small springs attached externally to the bent end prevent the fragments of tissue from falling into the larynx The instrument is inserted behind the palate, the spring between the handles being allowed to sep arate the blades as far as possible It is then pushed upward and closed, whereby everything pendant from the roof is snipped off as far as it gets into the grasp If the operator feels that the of the instrument

² Deutsche med Wochenschrift 1885 p 57² ³ Made by Sharp & Smith, 73 Randolph St, Chicago No unpleasant reaction has ever occurred in my experience There may be slight oozing of blood for a short while, but this has always been insignificant. The pain ceases within a few minutes. The wound causes often some congestion of the nasal mucous membrane, so that the nose is more stuffy during the first night after the operation, especially if remnants of the pharyngeal tumors are left behind. Rarely have I seen slight fever within the first twenty-four hours, and never longer than within this period.

Central Music Hall

ABDOMINAL SECTION FOR RUPTURED TYPHOID ULCER, AND FOR INTESTINAL OBSTRUCTION

BY R B BONTECOU, M D,

SURGEON TO THE MARSHALL INFIRMARY TROY NEW YORK

My attention having recently been called to an article on this subject in the *Medical News* of November 26, 1887, and also to another article in the same journal of December 24, 1887, by Prof Thos G Morton, of Philadelphia, I think it may be of interest to some to publish the following case, as I was not aware when I performed the operation that it had been done for that purpose

James Daley, æt 25 years, unmarried, of temperate habits, was taken sick at his boarding-house about October 1, 1887, and came under my care October 6, with high temperature, right iliac tenderness and gurgling, and with the other symptoms and general appearances of typhoid fever, which disease had been prevailing to some extent in the city He persisted in having on his clothes and sitting about the rooms for five days, trying to fight off the disease, but finally consented, as his lodgings were not suitable for a sick person, to go to the Marshall Infirmary, where I was His history, as given by the resident eon, is as follows James Daley, team house surgeon, is as follows ster, æt 25 years, admitted to the Marshall Infirmary on the evening of October 11, 1887, suffering from typhoid fever, with temperature of 102° tinued in apparently a comfortable condition, without complications, with temperature 102° mornings and 104° evenings, until the 15th inst, when he had a morning temperature of 104° and complained of On the 16th increased nausea and right iliac pain pain in the right iliac region and tympanitic condition of abdomen On 17th morning temperature 104°, hiccough and vomiting of prune-juice matter and bowels constipated and tympanitic, and still complaining of the abdominal pain, legs drawn up,

scissors have cut off the tumor, the blades are at once opened and applied in another position, if it is not completely detached, it is torn off by extracting the instrument and then reinserting it if necessary. With reasonable tolerance on the part of the patient, the operation can be readily finished in one sitting. The hæmorrhage is less than in curetting, and the entire operation does not last as long. I have never had any accident or unintentional wounding of parts, not even pinching of the palate, in the fifteen times I have used this new instrument.

cold, clammy perspiration, countenance pale and pinched and eyes sunken, was seen at noon by the attending surgeon, who diagnosed peritonitis from intestinal perforation

peritonitis from perforation, and stated the case fairly to him that he would certainly die, and to his question if anything could be done, replied that an operation, although offering very little hope, was the only thing left that could be done He consented As soon as the necessary preparations could be made he was anasthetized with ether and the section made under strict antiseptic rules in the median line On open ing the peritoneum a considerable quantity of flaky dark colored scrum escaped I at once went for the ileo crecal portion, and found perforating ulceration of the appendix near its base. I ligated this on the proximal side and removed it On further search I found an oval perforation in the ileum about ten inches from the colon and about one line in its long est diameter The intestine was apparently sound in the vicinity and elsewhere, but deeply injected and rather dusky in color No other perforation could be found I turned in longitudinally the portion of intestine including the perforation, and sutured its peritoneal surfaces by Lembert sutures and, after cleansing the abdominal cavity with a weak bichlo ride solution, closed the wound The man expired before he had recovered from the anæsthetic led to perform the operation on general principles, as the only thing to be done where intestinal perfora tion is recognized, appreciating the fact that it is a mortal accident, and that with the light and aid of antiseptics I have the faith and hope yet to save some case of the kind The operation cannot im pair the condition, and if the accident is recognized soon after its occurrence, there is a chance of suc Unfortunately, in this case, forty eight hours had elapsed after the first perforation Drs Lomax, W W Seymour, H Gordinier and N F Martin kindly assisted me in the operation

Note —The condition of the patient in this case was such that time was an important element in the operation, otherwise I should have practiced what I have before intended in cases of perforation of the appendix, and that is, after cutting off the process on the proximal side of the perforation, to invaginate the cut extremity and sew the peritoneal surface to gether with a close continued suture, thereby hoping to get a more reliable union of the parts than might obtain if the process was simply embraced in a ligature with the mucous surfaces in apposition

Abdominal Section for Intestinal Obstruction - Jas of temperate habits, ate baked beans on Monday, November 28, which made him sick, gave rise to colic that night, and had no passage from his bowels since 24th or 25th of November, but continued in pain of a paroxysmal nature which required large anodynes to mitigate He came under my care De cember 1, found him in bed suffering great pain, rethat could be relieved he would be all right I could

principles with poultices and anodynes of morphia and belladonna, and used large injections in the knee chest position which washed the whole colon out clean, and very little feculence was noticed I found him in collapse, with every indication of stomach tube was kept in place in the descending colon to permit flatus to escape His belly was at no time tympanitic, but was everywhere dull on percussion except in the track of the colon satisfied me that the small intestines were all full of frees which it was impossible to move, and that the obstruction was in the lower part of the ileum cember 7, his condition as to vitality being good, pulse 80, temp 99°, and unmistakable stercoraceous vomiting occurring, I obtained his consent to an operation, and at 9 o'clock in the evening, assisted by Drs Gordinier and W W Seymour and I W Morris, I made the operation with strict antiseptic precautions and, with a median incision of four or five inches, went at once for the ileo cæcal region and found the ileum tightly incarcerated under a diverticulum of the omentum about eight inches from the colon I put two ligatures on the band which formed the constriction and cut between them, liberating the gut, which presented when released, the appearance of an ivory ring about it, the constriction had been This was accomplished in nine minutes so tight from the commencement of the abdominal incision, some manipulations to coax the contents through the strictured gut occupied a few minutes more, and the wound was then closed by Dr W W Seymour, who used for the first time a very good mounted needle invented by him for the purpose of abdominal sutures Dry 10doform dressings were used and a broad bandage of adhesive plaster, completely encircling the abdomen and hips, such as I am accustomed to use for separation of the symphysis pubis after delivery, kept his parts comfortable and secure, and he at no time since betrayed any abnormal temperature or pulse He was from December 25 to 29 troubled with diarrhea, but is now well and dressed, and would be on the street were it not for the unusually cold weather (January 1, 1888)

Abdominal Section for Intestinal Obstruction -Mr Wheeler, æt 77, widower, retired merchant, of temperate habits and large physique, had been suffering obstruction for one week, and when called in consultation with Drs W H Hall and A Hewett found him vomiting stercoraceous matter, and was in a condition of collapse, with pasty skin The case was stated to him that he was dying and that nothing further could be done but an operation, to which he consented, and as soon as preparations could be made he walked from his bed to the dining room, E Evans, unmarried, et 24, occupation moulder and where a table had been prepared under the chandeher, and after ether and every antiseptic precaution had been taken the operation was done through a very adipose wall and the intestines all found quite empty, with no tendency to protrude I searched the ileo cæcal region first, and not finding any trouble there, ran the small intestine through my fingers until I reached close to the duodenum, and there found the ferred to the pit of the stomach, and he thought if loop, some inches in extent, closely strangulated, it was, however, easily released, and the abdomen make out no tumor there, and treated him on general cleaned and closed He was put to bed, had several

movements from his bowels, but never rallied from the collapse in which I found him I think he would have recovered if operated on a day or two earlier

Abdominal Section for Intestinal Obstruction -Kehn, æt 50, married, occupation pork butcher, in temperate, had obstruction several days, and when I was called in consultation, April 4, 1885, was in collapse and dying, having had stercoraceous vomiting The statement was made twenty four hours or more that nothing could save him but operation, and that that was doubtful, preparations were hastily made, and within half an hour I made the section through a fat abdominal wall and at once went for the ileo caecal region, which was found all right The constriction was found by a little further searching, in the lower third of ileum, and was easily relieved by gentle manipulation with the fingers The operation was made at 12 30 PM, and he did not rally from the collapse we found him in, and died at 3 P M the same Drs M H Burton, whose patient he was, and Drs Akın and Morris assisted me An operation a few hours earlier in this case would probably have portion contiguous to the gall bladder, and was insaved him

Abdominal Section for Supposed Perforation of the Appendia -- Mrs O, æt 45 years, a widow, in good health up to May 25, 1887, when she was seized with severe pain in the lower part of the abdomen, with great tenderness in the right iliac region and a bloated feeling all over the belly She applied poultices, took castor-oil, which operated, and kept her bed until May 29, when I was called and found her with tem perature 102° and pulse 115, abdomen tumid and very sensitive all over, but especially so in the right She maintained the dorsal decubitus iliac region Satisfying myself by digital ex with limbs flexed amination per vaginam and from her history that there was no hæmatocele, I concluded that there was peritonitis from intestinal perforation, probably of the It was difficult to learn by palpation the exact condition on account of the great sensitiveness, but manifest dulness all over the right iliac region and a faint sign of fluctuation seemed to indicate lo calized peritonitis with suppuration, and this was ver ified by aspiration May 31, when I proceeded, with the assistance of Drs W W Seymour and H Gor dinier, to cut down between the anterior spine of ileum and umbilicus, and getting through the abdom inal wall with an incision four or five inches in length, came upon a collection of pus mingled with fæces The pus cavity extended down into the pelvis, but appeared to be walled in by the adherent intestines on its upper and inner border, in fact, the parts all around were so infiltrated and matted together that I was unable to find (without unwarranted disturbance) the source of the feculence, and contented myself by cleansing the cavity and closing the wound over a rubber tube of large calibre The fever declined at once and in a few days disappeared altogether dramage tube was kept in place three weeks and the cavity washed out through it several times daily Feculence ceased to escape from the tube in ten days, and in one month she was able to walk a little, death taking place forty eight hours after the operaalthough she could not stand erect on account of in- tion There was no history or appearance of injury, testiual adhesions to the abdominal wall

els were moved with difficulty from the same probable September 20, 1887, an abscess made its appearance on the site of the abdominal wound, but healed in a few days after discharging its contents, The woman has which appeared to be simply pus since that time remained well and active

Abdominal Section for Obstruction of Bowels -Mrs R, at 52 years, mother of several children, was in ordinary good health up to November 25, 1877, when I saw her in consultation with her attending physician, Dr H C Murphy There had been complete obstruction of the bowels for twelve days On the 26th, 27th and 28th every means we could devise failed to relieve the obstruction, but the patient would not consent to an operation until Nov 30, when stercoraceous vomiting occurred and, the patient consenting, I opened the abdomen by a free median incision of the segment. In the lower segment there was great distersion of small intestine and ascending colon, and also a great engorgement of their The obstruction was readily found at the cluded in a scirrhous mass involving a portion of the Presuming this to be malignant, I did not attempt its removal, but brought the caput coli to the inferior angle of the wound and stitched a portion to the integument large enough to allow of a free opening being made in the gut and kept patent profuse discharge of fæces escaped at once through the artificial opening made, and continued until her death twenty-four hours later There did not appear to be any peritonitis, she was feeling well four hours before her death, when she accidentally discovered with her fingers the large pins which held the abdominal wound together, and she fainted and did not rally from the syncope or shock Antiseptic precautions were not used in this case

Explorative Abdominal Section -Mr M, et 74 years, a healthy, active man, was in his usual health up to thirty six hours before I saw him in consultation with Dr M H Burton, his attending physician, and with Drs W Akin, J W Morris, H Gordinier and Sabin, July 31, 1885 He was suffering great pain, and his position and rational and physical signs indicated peritonitis from perforation Bowels con stipated, abdominal walls haid and tympanitic, pulse frequent and feeble, and general indications of approaching collapse I made median section in the lower segment at noon July 31, and at once went for the ileo cæcal region, expecting to find perforation None, however, was found either in it, or the colon, or small intestine, or gall bladder. Turbid serum escaped in considerable quantity when the peritoneum was opened, and the intestines and reflected parietal peritoneum showed acute peritoni-The abdomen was washed out with a weak car bolic solution and the wound closed, leaving in its lower angle a drainage tube dipping down into the bottom of the pelvis, through which his abdominal cavity was irrigated with a weak solution of chlori-The peritonitis, however, continued, nated soda Her bow- and the cause of the fatal peritonitis is conjectural

Case 2 illustrates the advantage of early operative stage is by the administration of a purgative, I gave interference while the vital forces are good, for notwithstanding the serious character of the strangulation in that case, he made rapid and uninterrupted recovery, whereas in cases 3 and 4, the obstruction plapine, and a little ginger The patient had frewas from adhesions that were comparatively slight, quently used similar pills, prescribed by her own so that they were relieved by gentle manipulation, and jet the cases proved fatal, because operative interference was deferred until collapse was an Case I was in an almost hopeless condi tion when seen by me If I had operated on him on the 15th inst he would have had a fair chance of I hope soon to read of some one doing this successfully for typhoid intestinal perforation If you are sure that perforation has taken place, do not hesitate, for the operation cannot impair, but certainly improves the chances of recovery

MEDICAL PROGRESS.

ADVANTAGES AND RISKS OF PURGATION DURING CONVALESCENCE FROM ABDOMINAL SECTION -MR JOHN D MALCOLM records an interesting case bear ing on this subject. The patient, a woman, æt 57 years, had had an ovarian tumor removed On the evening of the third day, and all through the fourth day, there was a tendency to sickness and abdominal distension, but flatus passed freely from the rectum On the fifth day that portion of the bowel was found to contain feces, and a small enema produced a copious evacuation, after which the feeling of sick-The action of ness and the distension passed off the bowels was followed by considerable pain in the right groin about the position of the pedicle, and the temperature rose in a few hours to 100° in the axilla, but again gradually fell to 98° on the seventh day The bowels moved seven times beafter operation tween the fifth and tenth days, and much flatus also During this time, however, the pain in the right groin increased, until the patient could not bear the slightest pressure over this part The rest of the abdomen became slightly distended, but was free from tenderness The administration of $\frac{1}{60}$ of a grain of atropia and Tz of a grain of muriate of morphia, repeated every four hours, eased the pain, but the appetite became very bad, and the patient felt constantly sick after the eighth day She also lost strength, and her pulse, which had been down to 84 and of good character, gradually rose to 100, and became very feeble On the tenth day her temperature, which had not been above 98 6° for two days, also began to rise a little, and reached 99 6° in the axilla at 9 30 AM, she had been very restless all night, could not take any food, and felt very sick, while the abdomen had become more distended This grouping of symptoms after abdominal section I have learned to associate with obstruction in the bowels, which may lead to a rapidly fatal termination In the belief therefore that my patient of the case was in extreme danger from this cause, and that the best method of treatment of this condition at this real Society the Lancet Oct 29 p 860

her a pill containing 1/3 of a grain of calomel and as much jalap, a grain of compound extract of colocynth, I grain of extract of aloes, 10 of a grain of medical attendant, Dr Morley, of Blackburn, and they had moved the bowels gently during health On this occasion the pill produced two small loose motions, and a dose of Hunyadi water, given next morning, was followed by other loose motions last of these was at 5 PM on the seventh day after operation Twelve hours after the pill was given the temperature had risen to 100 6° in the axilla, perspiration was extremely profuse, and the patient had become alarmingly weak, but she was then able to take food without feeling sick After the bowels were quiet 20 minims of tincture of opium were given by the rectum, and the patient had a good night's rest She was much stronger next morning, and this improvement continued pain in the right groin, however, became more severe, and the tenderness radiated over the abdomen to some distance from this part The temperature continued feverish but irregular until the thirteenth day, when it fell to normal and remained so this day also the pain shifted upwards and towards the right loin, and next morning there was only slight tenderness on pressure in the groin, and none in the Now, however, the patient at once complained of pain when I applied pressure over the colon in the region of the gall bladder The seat of tenderness afterwards shifted from time to time along the course of the colon, and finally was found low down in the left groin, on the fifteenth day after the opera-The bowels had then been quiet for four days and I warned the patient that she would probably soon have an action of the bowels with considerable That afternoon several large, very hard fæcal masses passed into the rectum, whence they were removed with some difficulty by the nurse, after which recovery was uninterrupted

This case is very instructive in connection with the question of the administration of purgatives during convalescence from operations for abdominal It is evident that the masses of fæces which were removed on the fifteenth day after operation were the cause of all the difficulty and danger in this case, by producing a partial obstruction in the bowel The fæcal accumulation had been impacted in or near the cæcum, and the efforts of the bowel were insufficient to remove it, probably on account of the condition of paresis of the intestines which I have shown follows abdominal section, and is "an important factor in the production of obstruction of the bowels in these cases "1 When, however, the impacted mass was dislodged by the aid of the purgative medicine, the sickness and distension at once disappeared At the same time the temperature of the patient rose distinctly, and this in spite of a most profuse perspiration, pain in the groin became more severe and diffuse, and the patient's strength failed

purgation relieved a partial obstruction in the bowel, Morell Mackenzie observed that a patient after exbut at the same time increased, or rather renewed, tirpation of the larynx was usually in a condition "of the inflammation in and around the pedicle Many great misery" Professor Lefferts, of New York, cases have taught me that this is the way in which stated that the "main reason for the patient's subsepurgation may be beneficial during peritonitis after quent discomfort, not unusual, however, in like abdominal section may therefore be necessary, and proper treatment, | fect in the neck, by any form of artificial apparatus, but it is inaccurate to say that the purgation cures so as to permit of perfect deglutition" Since 1881, the peritonitis recognized that the administration of a purgative in such cases is resorted to at the risk of increasing the Still the frequency of fatal lung complications above severity of any inflammation implicating the wall of recorded is suspicious the gut, and in severe constipation, even when there remedied, more or less, by the use of an artificial has been no recent inflammation, a smart purge may produce a great deal of inflammatory action in and around peritoneal adhesions — Lancet, Dec 24, 1887

Partial Excision of the Larynx —The follow ing are the results of partial excision up to the pres-In twelve cases, where half the larynx was removed—in ten cases for carcinoma, in two for sarcoma—only one patient died from the direct removal is not very unsatisfactory, provided that the effects of the operation dress and the patient's condition less desperate than when the entire larynx is excised larynx has been completely, and in two partially, removed for sarcoma The after-history of one of plete excision for carcinoma, it is highly unsatisthe complete operations is lost, of the remaining six factory. As a rule, it appears to mean death, as it appears that one was quite well and free from recurrence six years after operation, one was well two years after, one died of phthisis a year and a half complications Truly a patient under such condiafter excision of the larynx, without a sign of recurrence of the local disease, one died of recurrence of the sarcoma seven months after operation, and one that none but fools would keep "-British Medical fifteen months after In the two recorded cases of Journal, Nov 19, 1887 partial excision for sarcoma, one was free from re currence "some time after the operation," one died ten months after from pulmonary complication, with Of the thirty out recurrence of the new growth five cases of excision for carcinoma which recovered from the operation (excision, as above noted, proved directly fatal to thirty patients), twenty died within a few months from recurrence Of the remaining fifteen, the history of one case is lost, two died of pneumonia at the end of three and four months respectively, seven cases were yet alive when these statistics were prepared, and free from recurrence at ease is absent in this affection, and most of the paperiods ranging from fourteen months to four years Thus only one patient could be considered cured Out of seven partial excisions of the larynx for cancer, one died of the operation, three died of recurrence within seventeen months, and in the three which remain there was no recurrence, but only four teen months had elapsed in one of these, eleven in another, and an unrecorded space of time in the It must be observed that many of the above cases appear to have been badly selected, the patient being in an unsatisfactory state of health, or the dis-Unfortunately, the survivors, ease much advanced not very numerous at the best, too often find but course of the day the amount of albumin in the urine little comfort in life after the operation Solis Cohen is subject to variations, which seems to follow cerremarked at the International Medical Congress in tain laws in every case, but are different in different London, in 1881, that recovery and mere survival cases

It is evident, then, that in this case after the operation are two different things, and Sir Purgation during peritonitis cases, was the impossibility of closing the large de-On the contrary, the fact must be cases have been noted where the patient's condition was not in any instance altogether unsatisfactory The loss of voice can be After partial operations the patient can often swallow easily within a few days, but after complete excision, with extensive removal of the surrounding parts, deglutition may be impossible without assistance, and the patient may need to be fed by means of a funnel and tube Altogether, excision of the larynx is a gloomy subject to con-For sarcoma, partial or even complete The wound is far easier to disease has not advanced too far Partial excision for carcinoma is also no desperate operation, but it has In six cases the not been performed with sufficient frequency to allow of a very decided verdict As to coman exception, it signifies a short but harrassed lease of life, with constant fear of recurrence and of lung tions may say of his life, like the Duke in Measure for Measure, "If I do lose thee, I do lose a thing

> CYCLICAL ALBUMINURIA — In his resume of an article on this subject in the Zeitschrift für klinische Medicin, Bd 12, Hft 1 and 2, G KLEMPERER, of Berlin, says

> Cyclical albuminuma is to be regarded as a well characterized type of disease It occurs most frequently in young people, and it seems that males are most subject to it Besides a somewhat anæmic and emaciated appearance there is no especially striking Every sign of Bright's dissymptom of the disease tients are nervous (neurasthenic) Their complaints are of an undefined nature pain in the head, weakness of the back, relaxation and uncomfortableness, want of energy, and indisposition to physical and Gastric troubles are often promimental exertion nent, such as loss of appetite, eructation after eating, and a feeling of fulness and distension symptom is the appearance of albumin in the urine, that is generally only accidentally discovered by an insurance or a military surgeon The entire absence of albumin in the night urine has been a common symptom in all the cases observed hitherto In Pavy's cases the albumin rose from roth

fell off to nothing again urine in these cases is free from albumin characteristic in these cases that the maximum peripheral vagi are in a normal state cases the maximum was noticed at 5 PM in the forenoon and one in the evening cyclus has been established it occurs, unless influenced by external cause, with great regularity The researches of Bull, Noorden, and Klemperer show that the time of taking food does not affect the time of appearance of the albumin But it seems certain that muscular movements have a great influence on cyclical albuminuma, for absolute rest will usually But muscular movements do stop it with certainty not always cause albuminuria in these cases, for in some of Noorden's cases as well as in Klemperer's case the urine remained free of albumin after long continued walking It seems also that prolonged and severe mental work may increase the albumin It seems, further, that good feeding has a good influ ence on the affection, and as the patient becomes more healthy and stronger the albumin diminishes The diagnosis can be made with certainty by a systematic examination of the urine for a few days, if the urine, not pathological in other respects, con tains no albumin early in the morning, and then has a regularly appearing amount of albumin once or twice during the day cycle, running from entire absence of albumin to a into the heart en masse maximum, and then failing off to nothing, having a Very characteristic is the lessening been reached of the albumin when the patient remains in bed dur ing a part of the day The neurasthenic symptoms often lead to an examination of the urine, and thus the true nature of the malady is determined history of the cases thus far reported shows that cyclical albuminuria follows a chronic course, but Pavy has seen two cases of spontaneous recovery It does not run over into renal disease, and is com patible with perfect health Some times it disappears entirely, while in other cases it persists for years without disturbing the general health The prog nosis is good. So far as treatment is concerned there is but little to be said. But it seems that a strengthening treatment, in which the anæmia and neurasthenia are made to disappear, will exert a wholesome effect in curing the albuminuria

Physiological Action of Arnica Montanum — DR H A HARE, of Philadelphia, says When a dose of from five to ten drops of the officinal fluid vein of a dog weighing from fifteen to twenty pounds, the pulse rate and arterial pressure are for a moment depressed, but in the course of from thirty seconds to a minute return to their normal position about five minutes however, the pulse beats become one third slower than they are normally, arterial

ing to the maximum very slowly, and then gradually the pneumogastric nerves be cut, the pulse instantly During the evenings the increases its rate considerably beyond the normal, It is though not to the point generally produced when the always occurs during the forenoon, but in Bull's ence was, however, more marked in some cases than In the in others We may therefore conclude that the case seen by Klemperer there were two maxima, one drug stimulates in small ordinary doses the vagal When the centre in the medulla, thereby producing a slow full pulse, and that it has an effect on the peripheral ends of the vagus, for the reason that when these nerves are cut, the pulse rate only increases somewhat That this failure of the pulse to become very rapid after vagal section is not due to cardiac depression, is proved by the strong pulse waves, and the increase in arterial pressure, rather than a fall

When a much larger dose (5 c c) is given to a dog of twenty pounds weight, the primary slowing does not take place, but in its stead the pulse becomes very rapid with a fall of arterial pressure, which, however, soon recovers itself, the pulse still remainirg rapid Under these circumstances it was found that galvanizing the vagus nerves, even for as long as one minute and a half, failed to produce any cardiac slowing, proving palsy of peripheral vagi, and this was also proved by the fact that when the vagi were cut and their peripheral ends stimulated by small doses, large doses immediately produced a rapid rate, but no more than a momentary fall of arterial pressure, lasting, perhaps, twenty seconds The variations follow a and due simply to the sudden entrance of the drug

Arnica therefore slows the pulse in ordinary medicsecond maximum after the second zero point has inal dose by stimulating the pneumogastrics both peripherally and centrically, increasing the fulness of each pulse wave, and also slightly the arterial press-That the increased arterial pressure is chiefly due to increased work done by the heart is strongly indicated by the fact that in none of the experiments was arterial pressure influenced to any extent, by any dose, except when an enormous amount (5 c c) was injected rapidly into the jugular vein, when there was for the space of from ten to fifteen seconds a fall in pressure very evidently due to momentary heart failure, as the pressure returned at once to normal as soon as the heart freed itself from the volume of the drug That the fluid extract used was pure I am confident since it was prepared by a reliable druggist especially for these experiments Boston Medical and Surgical Journal, Jan 12, 1888

RESECTION OF THE STERNUM FOR RETROSTERNAL ABSCESS -PRIVAT DOCENT J VON RUSTIZKY, of Kiew, reports the following interesting case in the Deutsche Zeitschrift fur Chirurgie, Bd 26, Hit 5 and 6 extract of armica root is injected into the jugular December 23, 1886, a man, æt 23 entered the city hospital He had always been healthy, and had never had syphilis On December 7, the third left molar tooth began to be painful, and soon there was In a swelling on the left lower jaw, which extended along the whole neck, and was most marked in the jugular fossa When he entered the hospital he pressure remaining unchanged, save that the pulse was so weak that he could not raise himself from the waves usually produced by inhibitory stimulation bed without assistance, pulse between 80 and 90, give it a greater range If under these conditions and evening temperature 38 5° to 39 7° C

right and left sides, at almost corresponding spots, the skin of the lower jaw were openings, and there defective and only partially covered the wound, the was another further under at the level of the upper part of the mediastinum was laid open, and thyroid cartilage, to the left of the larynx these openings flowed a considerable quantity of a brownish, bad smelling fluid, that streamed out on pressure and when the patient coughed Through the openings the finger could be carried easily under the surrounding skin, so that the denuded bone of the jaw and the pulsating vessels of the neck could The percussion sound of the anterior chestwall was dulled on both sides to the lower border of the third rib, over the sternum the dulness extended two or three fingers' breadth lower Over other portions of the chest the percussion sound was normal On auscultation of the upper portion of the thorax succussion was heard

On December 24, a median incision was made in the jugular fossa down to the sternum, and about half a litre of purulent fluid evacuated by the patient's coughing and by a low position of the upper part of the chest, so that the dull percuss on sound became tympanitic An elastic catheter passed 11 or 12 cm into the mediastenum, and the large pulsating vessels were easily felt with the finger cavity was washed out with a solution of salicylic acid, a thick drainage tube put in, and an iodoform dressing and a thick layer of sublimate gauze put on This was changed daily, and a solution of boric acid was used a few times The wounds of the neck were cleansed and dressed in the same way Under this hazel nut treatment the fever was kept down, the flow of pus became less, and the general condition much better But about the middle of January the patient began to complain of pains above the sternum and in the sterno-clavicular articulation, with severe chills and an evening temperature as high as 30° C of both sterno clavicular articulations was found, and less marked swelling, on both sides, of the sterno costal articulations of the first and second ribs The skin over the upper third of the sternum was red-Fluctuation was detected at the ends of the clavicles and of the first two ribs The outflow of that pus from the wound became greater, and the patient more emaciated

The second operation was performed on February The patient being completely narcotized, an incision was made through the skin and periosteum in the middle line of the sternum down to the ex tremity of the fifth rib, and another along the clavi-The periosteum was separated from the bone by means of a raspatorium, though some particles of The sternum was bone adhered to the periosteum impregnated with pus, and on the left side, at the second costosternal articulation, it was so thin that the removal of the periosteum here caused an opening through which, by means of a chisel, the manu- ment brium was separated on one side from the body of ulceration Kaposi, with reference to a case of the the sternum and on the other from the posterior pe-kind which he had published, proposed the name The manubrium was now raised, and lymphoderma perniciosa separated from the ribs and clavicles The posterior term which they have chosen — leukæmia cutis riosteal layer periosteal layer of the upper part of the sternum was They consider that this affection is distinct from bone removed by means of Luer's forceps Since French -London Medical Record, Dec 15, 1887

the posterior layer of sternal periosteum was very From the pulsation of the great vessels was distinctly seen There was slight hæmorrhage from a cutaneous vein, but it was checked with torsion pinchettes granulations (membrana pyogenica) were scraped out with the sharp spoon, the horizontal incision united by continuous suture, and the whole wound filled—after being douched with salicylic solutionwith iodoform gauze and covered with sublimate The patient was shown at Society of Physicians of Kiew on March 27 At that time he was well, and had no circulatory or respiratory disturbance, though the thorax was considerably retracted The shoulders were nearer together, and the sternal ends of the clavicles and the ribs almost touched The sternal defect was closed by a firm cicatrix After the operation the first and third left molars and a sequestrum of the lower jaw were removed

Louremia Cutis — Hochsinger and Schiff (Viertelj fur Derm und Siph, 1887, 3, Heft) add another to the few cases already published, in which the skin was the seat of lymphomata A child, 8 months old, badly nourished, and with great pallor of the skin and mucous membranes, had over the whole body, but particularly on the skin of the face and head, numerous nodular, flattened, rounded seats of infiltration of the size of a pin's head to a They were movable with the skin over the subcutaneous tissue, were firm, of a yellowish-1ed color, and not tender Some of them were depressed in the centre There was slight desquamation over some of them, but they were neither excoriated nor ulcerated. The sub maxillary, cervical, axillary, and inguinal glands were hard and The spleen and liver were enlarged, and swoolen there was a moderate amount of ascites corpuscles of the blood were proportionately in-A histological investigation was made, and creased as the result of the investigation the authors state In the course of leukæmia the cutis, as well as the internal organs, may be the seat of secondary leukæmic lymphomata 2 The lymphatic infiltration begins in the blood-vessels which surround the sweat glands 3 The fat lobules lying immediately under the cutis are the chief seat of the disease, the upper strata of the corium being relatively free 4 The external manifestation of leukæmic infiltration of the skin is that of a small nodular affection of the cutis, which usually appears after leukæmic affection of the lymphatic glands At the same time a previous condition of chronic inflammation of the skin, if accompanied with stasis of the lymph, may lead to diffuse and early affection of the integu-The nodules show little tendency to 5 The authors prefer the then separated from the bone, and this part of the mycosis fungoides or lymphodermie cutanée of the

MEDICAL LEGISLATION

The necessity for greater uniformity in the laws of the several States intended for the regulation of med ical education and practice, is becoming annually more apparent During the last ten years several States have followed the example set by the Legislature of Illinois, and enacted laws creating State medical boards authorized to grant the license to practice medicine in all its departments, to such persons as should present a diploma from a legally established medical college in good standing, without further examination In Illinois, Indiana, Michigan, Iowa, and perhaps some other States, the verification of the diplomas and the standing of the college granting it, was left to the judgment of the State boards But two or three years since the Legislature of the State of Pennsylvania enacted a law creating a State Board and authorized it to grant licenses to practice on the presentation of a diploma from any one of the legally established medical colleges of that State, while all persons presenting diplomas granted by medical colleges located outside of Pennsylvania, were required to go before the Faculty of some one of the medical colleges in that State for the verification and endorsement of such diploma, before the State Medical Board could issue to them a license to practice In plain terms, the graduate of the Medical School of Harvard, or of the Medical Department of the University of New York, or of the University of Virginia, or of any other medical school in this or other countries, outside of the Commonwealth of Pennsylvania, must fee a medical col-

before he enters upon the practice of his profession in that State Of course such a law could not long exist in one State without bearing fruit Hence we find in a law enacted by the Legislature of the State of New York, bearing date June 23, 1887, the following provision "Graduates of American colleges outside of the State of New York, and those holding licenses to practice from European governments, must have their diplomas or licenses endorsed by the Faculty of an incorporated medical college in this State (New York), or by the Regents of the University, on the recommendation of a legally constituted Board of Medical Examiners in New York endorser may require applicants to verify their statements under oath, and any endorsement made fraudulently, with gross carelessness or ignorance, is a misdemeanor, punishable by fine " While the law does not so state, it is understood that the applicant for an endorsement of his diploma will be charged \$25 by the endorsing college On the other hand, the laws of Alabama, North Carolina, Virginia, and Minnesota, have established in each of those States a State Board of Medical Examiners, and require all persons proposing to commence or to continue practicing medicine in those States to be actually examined in all the branches of medicine by such examining board, without regard to any medical college diplomas whatever, and to receive a license, provided the results of the examinations prove satisfactory to the Board Sec 3 of the Minnesota law, that was quoted in The Journal for January 7, 1888, not only requires "All persons hereafter commencing the practice of medicine and surgery in any of its branches" in that State to submit to a thorough examination by the State Board and receive a license, but they must "present evidence of attendance on three courses of lectures of six months each" If the first two lines of this Section are to be construed literally, and apply to all practitioners coming from other States as well as to young men just entering upon practice, as claimed recently by a correspondent in that State, the last clause just quoted makes it very nearly a prohibitory statute against any of the older practitioners educated in this country, from entering upon the practice of their profession in that State, simply for the reason that prior to the last two decades there were very few medical colleges in this country giving annual courses of lectures of six months' duration If the current methods and tendencies of medical legislation by the several States should continue, it will soon become as expensive and quite as vexatious for a practitioner to change lege in the latter State for a verification of his diploma his residence from one State to another and continue

his practice in this country, as it is for the traveller of capital punishment, and asking for suggestions in to get himself and baggage through half of the custom-houses of Europe Sec 3 of the Minnesota law, with two or three additions as we indicated in THE JOURNAL of the 7th inst, is an excellent provision to be applied to all persons just proposing to enter upon the active duties of the profession the facts we have mentioned above show very clearly that the profession of the whole country cannot too soon enter upon an active and persistent effort to procure more harmonious and efficient laws for the regulation of medical education and practice in all the States And much interest will be felt in the report of the committee appointed on that subject which is expected at the coming meeting of the American Medical Association in Cincinnati

HUMANITY IN THE DEATH SENTENCE

It is now about a year since a State Commission was appointed in New York, to investigate and report on the most humane and practical method of carrying into effect the sentence of death Commission, of which MR ELBRIDGE T GERRY, President of the New York Society for the Prevention of Cruelty to Children, was chairman, has completed its work and has just presented to the State Legislature its report, a pamphlet of almost a hundred pages, that bears witness to the commendable zeal and industry of the Commissioners methods now in use among civilized peoples for executing criminals not one can be called humane and The principal devices for this purpose are the guillotine, the garrote, and the gallows first two are practical but not humane, while the gallows is neither humane nor practical

Inasmuch as it has been pretty thoroughly shown by experiment in several States, that there is no sub stitute for capital punishment, the deterrent effect of which is so great, it is a matter of no little importance that that punishment should be so inflicted as to do away with the objections that have been raised by sensitive and humane persons against the methods now in vogue In doing their work the Commission seems to have been guided by the intention, as it has been expressed, of keeping the terrors and doing away with the horrors of the death penalty, and all the changes it suggests in the law have this When it was appointed it laid out a end in view system of work that provided for the practical exhaustion of the subject A circular was sent out, especially to judges, district attorneys, sheriffs, and physicians, soliciting views upon the present mode

regard to some more humane method than hanging, opinions being especially solicited in regard to electricity, prussic acid or other poison, the guillotine, and the garrote About two hundred replies were received, and after a careful consideration of these, and much outside inquiry and study, the Commission decided in favor of electricity, and forfeiture of the body as well as of the life of the executed criminal

In order to make the whole matter more intelligible, the report contains an account of the various methods of punishment employed since the Mosaic era, and the essential conclusion arrived at from this data, is that undue or peculiar severity in the mode of inflicting the death penalty, does not operate to lessen the occurrence of capital offenses the present methods the guillotine is regarded as too bloody, the garrote as too barbarous, and shooting as too uncertain and revolting except in military ev-Hanging is condemned for several reaecutions the possibility of resuscitation, the revolting scenes at bungled hangings, and the public feeling against the hanging of women The Commission believes that if instantaneous and painless death could be assured, not one of these objections could be urged against the death penalty

The Commission is satisfied that the electricity will fulfil the desired end, because medical and scientific authorities are almost entirely agreed as to its efficacy for the purpose Resuscitation after the passage of a strong electric current through the nerve centres would be impossible, and death would be instantaneous and painless

It is proposed that the criminal to be executed shall be placed in a chair having metallic head and foot rests connected with electrodes If the current be supplied from electric light wires the connection A separate wire from an could be easily made electric light plant would cost \$250 to \$500, and the chair \$50, while the cost of maintenance and opera-It is recommended tion would be merely nominal that electric appliances be placed in the State prisons at Sing Sing, Auburn, and Dannemora, and that all executions be made at one of these places In this way the prompt and efficient carrying out of the death sentence would be secured in all cases, while under the present system, by which each county hangs its own criminals, an entirely inexperienced sheriff is often called upon to superintend an execution, and the risk of bungling or failure is in creased if the duty be revolting or novel to him

The Commission expresses very positive convic-

tions in regard to the time of execution and the disposition of the body of a criminal In its opinion the prisoner should be doomed from the hour of his sentence, kept in solitary confinement, and executed without publicity on a day to be set by the prison warden, the time not to be less than four weeks and not more than eight weeks after sentence death the body should not be paraded like that of a hero, but should belong to the authorities for dissection or destruction, or if given to the family, the law should forbid the exhibition of it Criminals, it is held, meet death with bravado when they contemplate elaborate descriptions of their execution in the public papers, and ostentatious funerals afterwards, and the effect of all this is to lessen the horrors of crime and of the death penalty other hand, it would seem that by shutting a con demned criminal from the world at the time of his sentence, leaving him to the sternness of the law, with the knowledge that punishment was inevitable, capital crimes would become fewer sion suggests that the present laws be so modified that the changes may go into effect by January 1, 1889

THE SURGICAL TREATMENT OF PERFORATION PERITONITIS

In connection with the paper of Dr Bontecou, in this issue of The Journal, may be mentioned a case published by Lucke, of Strassburg, in the Deutsche Zeitschrift fur Chirurgie, of November 30, 1887 (Bd 26, Hft 5 and 6) The case was one in which the patient began to collapse suddenly after drinking a glass of cold beer Kussmaul advised an operation, and it was done by Lucke at 8 P M The spray was used for a quarter of an hour before the operation, warm sublimate compresses being placed on the ab Dimethylacetal chloroform was the anæsthetic used, Lucke preferring this in all operations on the abdomen The abdomen became somewhat relaxed under the anæsthetic, and a somewhat increased resistance was found on the right side, though there was no dulness The incision was made in the median line below the navel, and when the perito neum was opened a quantity of pus, mixed with flocculi of lymph, but containing no fæces, and a small quantity of gas, escaped The portion of intestine that pressed up into the wound was markedly in jected, distended, and here and there covered with fibrin flocculi, easily washed off A fenestrated drainage tube carried into Douglas' sac drew off a quantity

about 500 ccm The ileo cæcal region and the appendix were found free from perforation foration was found anywhere This operation was performed on April 24, 1887, and on June 17 the patient got up, having no fever, but with localized tympanites in the region of the liver Kussmaul and Lucke agreed in the diagnosis that the perforation had taken place through a small ulcer, by which only a minimal amount of intestinal contents escaped and set up an acute purulent peritonitis The site of the perforation was probably in a portion of the intestine in the right hypochondrium, and the perforation soon closed, but a localized peritonitis of slow development was set up, which afterwards caused pain and tympanitis On June 22 the patient complained of renewed pain, and other symptoms followed rapidly Soon there was dulness for 3 or 4 inches below the free border of the ribs, upwards to the fifth rib, and reaching to the middle line The pulse was 110-118, pains in the hepatic region, and appetite less June 28 the temperature went up to 389, on the next day respiration was distressed, the dulness was as high as the fourth rib, and puncture under the border of the ribs gave pus On June 30 an incision 5 cm long was made parallel with the free border of the ribs on the right side, and about 3,000 ccm of pus evacuated Through the wound the upper diaphragmatic surface of the liver could be felt, above the costal pleura, and below the finger passed through an opening towards the abdomen, and by pressure with the other hand a quantity of pus was evacuated A large drainage-tube was put in, and the wound dressed with iodoform gauze It is most probable that a sacculated peritonitis had been set up on the right side, the starting point being the seat of the former peritonitis, had penetrated the diaphragm, and ruptured into the pleural cavity The drainagetube was thrown out, and the wound caused so much trouble that on July 18 1t was enlarged, a portion of the seventh rib was resected, and a large quantity of pus escaped From this time the patient went on to recovery

there was no dulness The incision was made in the median line below the navel, and when the pento neum was opened a quantity of pus, mixed with floculing of gas, escaped The portion of intestine that pressed up into the wound was markedly in jected, distended, and here and there covered with fibrin floculi, easily washed off A fenestrated drainage tube carried into Douglas' sac drew off a quantity of pus, so that the whole amount of pus removed was

That there was perforation in this case there is no in many ways, in which abscess formed and death But had the case come under the care of some that believe that Nature can set a broken bone, or put a Lembert's suture in an intestine perforation, or scrape out a tuberculous abscess cavity, there would have been a labored argument, in the notes on the autopsy, to show that there was no perforation. and that an operation could have done no good The difference between Lucke's case and one of more extensive perforation is great, but it is one the profuse menorrhagia that had been present for rather of degree than of kind

SOCIETY PROCEEDINGS.

GYNÆCOLOGICAL SOCIETY OF BOSTON

Stated Meeting, September 17, 1887

VICE PRESIDENT, H C WHITE, M D, IN THE CHAIR

Dr. Mary E Bates reported a case of

UTERINE FIBROMA WITH PELVIC CELLULITIS

A widow, 46 years old, slim and anæmic the mother of one child, had been subject to menor rhagia for several years At intervals she had had attacks of pain in the right inguinal region which subject continued several days and in one instance a week Physical examination revealed a tumor as large as a that Dr Ephriam Cutter was not present, as he had hen's egg, a movable uterus, absence of metritis and the difficult passage of a sound Diagnosis Interstitial fibroid at the right side of the fundus days later the patient was taken with pain, nausea, profuse diaphoresis and anorexia Diagnosis peri tonitis Problematical and eligible causes the pres ence of the tumor, the menstrual period, unusual physical exercise and the difficult passage of the sound Improvement came on and a month later menstruation with the same symptoms again recurred Physical examination then showed the uterus fixed in an oblique position, the bladder pushed to one side, the abdomen hyperesthetic, the inguinal glands enlarged and tender and a "bunch" in the left inguinal After the menstruation ceased fluctuation There was a appeared in the left inguinal region rise of temperature but no definite chill Diarrhœa occurred in the place of constipation, the fluctuation and bunch in the inguinal region disappeared and Considerable drug pus was discharged from the vagina improvement has since taken place

DR H O MARCY said that he had seen the patient in consultation and had agreed with Dr Bates in the diagnosis He was at that time fully satisfied from the history of the case that pelvic abscess was to be expected

several years ago which resembled the one reported at present the patient has passed the menopause

resulted from exhaustion He thought that ergot or ergotin might be of use In 4000 cases under the observation of Prof Nelson 256 derived benefit from Dr Nelson believes that failure the use of ergot may be expected in subperitoneal cases but that the best results from the use of ergot are secured in the submucous tumors Dr Apostoli has showed that the diminution in size of fibroids after electrolysis is due to shock

DR BATTS, in reply to various questions, said that several years first led her to suspect a myoma At first she had made no measurements as no tumor was Dr Bates knew nothing so liable to suspected cause the abscess as the tumor itself, though the patient attributed it to the passage of the sound Ergot had been tried in this case

DR A L Norris said he had been much interested in the valuable paper of Dr Bates He remem bered a case of the kind complicated with peritonitis and multiple abscesses when there was great exhaustion and a fatal termination The patient was 32 years old and had never borne children although she had had several miscarriages with subsequent debility and chronic induration He said he had used ergot in both submucous and interstitial fibromata several In two cases it was attended with marked success, not only controlling hamorrhage but ablating perceptibly the growth, which after five months ceased to cause trouble The lack of time prevented him from reviewing data, otherwise he could have narrated more cases of interest bearing upon this

DR W Symington Brown said that he regretted originated the treatment of fibroids by electrolysis in 1870 and had demonstrated the decomposition of raw Dr Cutter beef and a fibroid tumor by electricity operated upon an extensive fibroid in a patient at Stoneham, Mass, after which operation the tumor diminished to one-half its original size and the patient was restored to health Dr Cutter uses a battery of six large cells which he prefers to a large number of small cells He has cured eighteen or nineteen cases, six of which are known to Dr Brown Dr Brown believed that many tumors called fibroids are not fibroids, but hæmatoceles He considered laparotomy the true treatment for fibroids If the patient is comfortable no operation should be done, but in a case like that of Dr Bates laparotomy should be performed to relieve the flooding Dr Brown had treated two cases successfully with Squibbs' ext ergot, fl

DR F L Burr believed that many failures in the use of ergot were due to the poor quality of that drug He has sometimes used it by saturating cot-

ton and applying it to the vagina

Dr H C WHITE considered the mouth the best and most natural way to give ergot He has at present a case of fibroid where the patient measures 48 inches about the umbilious and the tumor is supposed be expected

DR A P CLARKE said that he had had a case advised removal Ergot controlled the flooding and Stated Meeting, October 13, 1887

DR WILLIAM G WHIFLIE IN THE CHAIR DR A P CIAKKI read a paper entitled,

A CASE IN WHICH ABORTION WAS INDUCED TO REI II VL UNCONTROLLABLE VOMITING OF PRECNANCY

(See p 40, Journal of Junuary 14, 1888) DR J F FRISHIF described a case that had fallen under his observation A young Prince Edward's Island woman became pregnant soon after marriage and suffered from severe nausea and vomiting for six weeks, at the end of which time vomiting was checked Pregnancy went to full term and a healthy child was born which died some months later The following soon appeared which defied all measures for its relief The mother was reduced to a skeleton and was con fined at eight and a half months The child weighed at the fifth month of pregnancy but 4 pounds and consisted of but little more than skin and bones The mother lived but has never Dr Frisbie was of the opinion been well since that the interests of both child and mother might have been best subserved by the induction of abortion at an early period in the pregnancy

DR CLARKE in reply to Dr Mary Bates as to the urine was heavily loaded with urates

DR BATES described a case of a patient who sought her advice for chronic metritis there were no casts in her urine She subsequently became pregnant and passed out of Dr Bates' care consultation, and found that she had been ill for seven months, and had been vomiting constantly for four weeks The patient was evidently in a critical condition and Dr B advised the induction of abor tion, but this advice was not accepted by the attend In one hour convulsions set in and death oc curred at the end of three hours The urine was found to be one half alhumen and to contain abundant old casts At the autopsy urea was found in the stomach, it had also been deposited in the cere Dr Bates wished to ask the opinion of the members of the Society as to what would have been the proper course of treatment in this case, whether it would have been best to have given pilocarpine and used active means to relieve the kidneys, or to have at once induced abortion?

DR L F WARNER said that he did not regard the cases described by Dr Bates and Dr Clarke as at all The vomiting in Dr Bates' case was probably uremic in its nature and not what is usually known as the vomiting of pregnancy It was not the direct result of the pregnancy but was one of the indirect effects of that condition, probably pres sure on the kidneys or on the blood vessels belonging In such a case there are other and better abortion

DR I W STARBIRD, in referring to the case de

by assisting in the elimination of the urea which was causing the trouble. The use of the steam bath and active cathartics are the best and quickest means of accomplishing that end If these measures fail premature delivery should be resorted to

DR C W Sievens mentioned a case that had been under his care recently. The patient was a lady of 37 years, and married for the second time had been pregnant three months, during the last six weeks of which time vomiting had been excessive She was confined to the bed and fainting followed any effort to rise Her prostration was extreme The induction of abortion was decided on as a last resort, and it was accomplished by the use of a bougie A fœtus 3 or 4 inches long was expelled, no year the mother again became pregnant. Vomiting hamorrhage followed and recovery was rapid and complete

DR L F WARNER described a case that he saw The patient was in a wretched condition and vomited everything There was a jaundiced condition of the whole body Small doses of calomel, specac and hyoscyamus were The patient was directed to eat all she wished and if that was rejected to eat more. She was soon able to retain her food for a period of time which gradually lengthened In a month she could whether there were any casts in the urine of the pa- retain her food two hours, and in the end she made tient said that there were none at any time but that a good recovery In such cases it is necessary to start up a healthy action of the liver When this end is gained the progress toward recovery is sure At that time Warner said that he had never induced abortion in such cases and he had never lost a case

DR HELEN WEBSTER recalled a case that she had At a later date Dr Bates was called to see her in lost fifteen or sixteen years ago. The patient was of neurotic tendency, suffered much from neuralgia and was in a bad state generally She had aborted once previously She again became pregnant and vomiting was frequent and severe She became extremely emaciated and the skin assumed a yellow Abortion was suggested and advised but the consulting physician advised against it The patient gradually sank and died She aborted two days be-During the last forty eight hours she fore death was delirious and counted 1, 2, 3, 4 incessantly In a similar case Dr Webster would now induce an

> DR F L Burt believed that abortion was sometimes done in these cases where milder measures would be successful He also believed that active interference was often delayed until too late a period to be of any avail Medicinal means should be tried long and faithfully, but when time has demonstrated their uselessness more radical measures should be at once used

DR W S Brown said that Dr Warner had introduced an important distinction in these cases of persistent vomiting The first question to be settled in these cases is, Is the vomiting due to the pregnancy or to some other morbid condition? Dr B had means of relieving the kidneys than the induction of learned to pay particular attention to the liver and had made frequent use of the hepatic pill, so called Much of the dissatisfaction from the use of calomel scribed by Dr Bates, said that in such a case he has arisen from an unintentional adulteration of the would first use heroic measures to relieve the system drug with the corrosive chloride. This results from its

not having been thoroughly washedduring the process solute quiet and rest, yield the best results of manufacture Pure calomel is one of the safest bromides and opium seem to have the most beneforms of mercury which we have at our command, ficial effect but its adulteration with the corrosive chloride has given rise to most of the accidents which have terested in this paper, and while I am not prepared brought discredit upon the drug If Dr Clarke made any mistake in the case reported it was in waiting too long before interfering When mild remedial meas ures fail it is a mistake to delay The principal reason why the Cæsarian section is so often fatal in this country is that the operation is generally delayed recovered. It is probable that this is a very small until the patient is moribund. This operation ought percentage of the whole number, it seems to me to be nearly as successful as ovariotomy if it was per- that it is a common disease. I have had ten cases formed under favorable circumstances As a rule the operation of tracheotomy is delayed too long to practice offer any chance of recovery In inducing and abortion Dr Brown has abandoned the use of the bougie He now dilates the neck of the womb by the use of a tent the sides of which have been protected by pieces of slippery elm bark When dilatation has in this way been begun he uses a dilator and rapidly opens the neck to the required size. The advantage of this procedure is that you can thus deliver both fœtus and placenta without delay

CHICAGO MEDICAL SOCIETY

Stated Meeting, November 21, 1887 THE PRESIDENT, W T BELFIELD, M D, IN THE

DR L L McArthur read a paper on THE PRESENT STATE OF TETANUS

Tetanus is divided into acute, subacute and Every case of tetanus has, as a primary factor, a traumatism which may be no more than the prick of a hypodermic needle or may be the crushing of a limb Blacks are said to be more liable to tetanus than whites taken into consideration, hostlers, gardeners, etc., being especially susceptible to the disease claimed that tetanus is always infectious and never the amount until the man took 3 grains every dose, spontaneous. The case was mentioned of a New of the stock which was in the hospital, without a York surgeon, who, when making a post mortem examination of a horse that had died of tetanus, accidentally scratched his finger, and shortly after died Experiments have been made of the same disease by which a microorganism cultivated from garden teristic symptoms of physostigma poisoning-pinsoil and introduced under the skin of animals, produced tetanus, and muscular tissue obtained from a lungs with rapid superficial breathing I gave the case of tetanus introduced under the skin of lower usual antidotes, atropine and digitalis, and he soon Out of 16,000 recovered, the first thing he did was to assume the animals reproduced the disease cases of foot injuries during the War of the Re In 12,000 covered, but he never regained his strength of mind bellion, fifty-seven resulted in tetanus hand injuries not a single case of tetanus was re- - he was simple, had a peculiar laugh, and talked a In the acute stage the termination is always great deal, before he had been a silent man, but he fatal by the end of the fourth day from spasm of the became very garrulous and was the clown of the larynx or heart failure In the subacute, there are ward The chronic form sight of him Another case of interest occurred 50 per cent of recoveries terminates favorably in from thirty to sixty days In while I was house surgeon A man was brought to the treatment nervous sedatives, combined with ab- the hospital with a simple fracture of one tibia, in

Dr A E HOADIFY I have been very much into contribute anything in the way of theory as to the pathology or etiology of this disease, I am surprised to see how few cases have been cited, but seventyseven having been collected, then again, I am surprised to learn that fifty four out of the seventy seven of traumatic and four cases of infantile tetanus in my

DR N P PEARSON Yesterday I received a medical paper from Copenhagen, in which I saw a report of a case of infantile trismus They have found bacteria They took a part of the navel and produced infection from it, they infected mice and guinea pigs,

and they died immediately of tetanus DR FRANK BILLINGS It may be interesting to cite two or three cases that have come under my observation, especially as to the treatment Cook County Hospital, there were, I remember, two cases of especial interest to me One was a man about 30 years of age, who had received an inoculating wound from a pitch fork, through the foot, passing downward from the dorsuin He did not come to the hospital until trismus had commenced The wound in the foot was suppurating then, and Dr Meacher, of Portage, Wis, who was house surgeon, opened up the local wound and dressed it an-Tetanus developed, and on the third tiseptically day after he entered the hospital the sciatic nerve of that side was stretched It did not have a good influence, and three days afterwards the crural nerves were stretched, and after that the sciatic nerves were again stretched, without marked effect good or At the same time he was put upon morphine and chloral, afterwards he was given the treatment The occupation must also be recommended by Dr Gunn-hypodermic injections of physostigma We began with 1/8 of a grain re-It is peated every three hours, and gradually increased The stock giving out, a new perceptible effect supply was obtained, and the nurse went on giving 3 grains of the new supply I was called suddenly to see the man, and found him with all the charac-

point pupils, and rapid, weak pulse, cedema of the

tetanus position-opisthotonos He eventually re-

He disappeared from the hospital and I lost

two weeks trismus suddenly developed after a chill On examining the man, I detected fluctuation over the seat of fracture and the bones were freely mova Dr Isham was the attending surgeon wound thoroughly, and although the trismus remained for several days, the man ultimately recovered, with perfect union of the bones Another case—which is not of special medical interest—was a boy who received a crushing injury of one leg amputated the leg in its upper third, the flaps united very well, but about the seventh day he was taken The friends of the boy consented to have the sciatic nerve stretched but when we at tempted to have it done—had the boy carried into the operating room, the warden and chairman of the hospital committee interfered and commanded us to take the boy back, as a result, the old medical board stepped out of the County Hospital afterwards stretched the nerve and the boy recovered -making three recoveries from tetanus during my service in the hospital Several other cases of tet anus occurred from 4th of July pistol wounds, and death followed in every one The temperature just before and after the death was the same as in all hydrophobic patients-it rose toward death, and my

Dr J A Robison Last summer, during my service in the County Hospital, there was a case of tenanus developed in my ward The man was brought in May, with what was supposed to be cerebral meningitis, he had a high temperature, face flushed and of a purple hue He was easily ex cited, and in a day or two we noticed symptoms of tetanus, trismus and ophisthotonos occurring during the progress of the case During the January previ ous, he had received a wound from a buzz saw in the second and third fingers of the right hand He was sent to the surgical side and these fingers were am For several days it was a question whether or not he would recover, but he finally did recover, and the last I saw of him he was walking about the ward, although he was insane I think the amputation probably saved his life, because these fingers were undoubtedly a source of irritation, as he would have tetanic spasms only when these fingers were This would seem to indicate that it is pos sible that old wounds act as an exciting cause of tetanus

DR L L MCARTHUR In regard to the frequency of recoveries in the cases reported, of fifty four out of seventy seven, I would say that it is probable that the cases which terminate successfully find their way into the medical journals, while those that terminate fatally are not so frequently published, and this will explain the apparent excess of cures over deaths To say that the disease is a frequent one I think is a mistake-it is one of the rare dis eases, although one sees it occasionally in practice During the entire war there were reported 28,000

cent), thus showing that the disease is not very frequent I am glad to learn that tetanus has been proven to be of an infective nature, because this We offers the best explanation of the causation of this made a compound fracture of it and drained the disease that has yet been given. Several eminent authorities have defined tetanus as a disease of uncleanliness, which would rather point toward its infectious character In the case reported by Dr Robison, he admits that there was a meningeal doubt in the case, and I think in many cases of socalled tetanus, investigation would prove them to belong to a different class of nervous diseases with a chill, and trismus commenced, and then tetanus point I think well worthy of emphasis, that is the continuance of the treatment long after all the symptoms of tetanus have disappeared, and I very much regret, in the last case which I had, that I diminished the amount of medicine that the man was taking, during an apparent improvement in the course of the disease Several French authorities also urge We this point

DR W T BELFIFLD reported a case of

NEPHRO-LITHOTOMY

James F, 37 years old, gives the following his-Some fifteen years ago he suffered for several months from great irritability of the bladder, urinating very frequently and with considerable pain thermometer, which registers 110° F, would not several occasions he passed blood. Was treated at register it. These symptoms gradually disappeared, at intervals thereafter he suffered from dull pain in the loins, often extending upward to the chest and sometimes incapacitating him for work For the past two years pus had been seen in the urine constantly in varying quantity At times the amount would be small for a few days, during which time the pain in the side became severe, then a large quantity of pus would be discharged while the pain diminished After treatment for various complaints he came, about a year ago, under the care of Dr Frank Billings, who discovered an increased area of dulness over the left kidney, and at times a distinct, though slight, swelling in the loin that the left kidney was the seat of suppuration, Dr Billings endeavored to ascertain the cause therefor Tuberculosis was almost certainly excluded by repeated examinations of the pus for the characteristic bacilli, with negative result As renal calculus seemed the most probable diagnosis, Dr Billings referred the patient to me for operation ough examination and observation this seemed to me also the most plausible diagnosis, though many of the acute symptoms of calculus did not then ex-The right kidney could be felt through the abdominal walls and seemed normal, but previous to the operation, I endeavored to demonstrate its integrity by closing the ureter of the one under suspicion, by means of Silbermann's catheter instrument caused so much pain, however, that the result was unsatisfactory June 26 last, in the presence of Drs Billings, Hosmer and Tilley, I explored the left kidney through an oblique lumbar incision The organ was found to be enlarged and flabby wounds of the hands and feet, and of these only Upon incising the cortex an explanation of this confifty seven resulted in tetanus (1 e 1 2 of 1 per dition was found in hydro nephrosis, only a shell of

the renal tissue half an inch thick, remaining cause of hydro nephrosis was found in a calculus of conical shape some two inches in length, its smaller end impacted in the ureter so tightly as to require some force for its extraction A few loose flakes were afterwards removed from the pelvis and ureter covery ensued without notable event On the fourteenth day the patient visited his place of busi In two months his weight increased from 105 to 123 pounds, and all morbid symptoms had disappeared except that some pus was still present in the Latterly this has become so slight in amount as to be discoverable only with a microscope sumably the shriveling of the distended kidney is about accomplished. The stone is an oxalate or mulberry calculus, and weighed 224 grains

DR Belfield also reported a case of

CANCER OF THE PROSTATE

Hans J, aged 48 years, was admitted to the County Hospital, suffering from unduly frequent and somewhat painful urination Symptoms which had existed for some three months On two occasions blood had been observed in the urine tion per rectum showed a slightly enlarged, though symmetrical prostate, along the centre of which, instead of the normal depression, was a slight protuberance By the microscope we found in the urine a few blood corpuscles A tumor of the pros tate, either epitheliomatous or malignant was diag-The latter seemed more probable because the quantity of blood in the urine was altogether too slight for the benignant variety Efforts to entangle and bring away shreds of the supposed growth in the eye of a metallic catherer, failed May 7, the blad der was explored by supra pubic incision, and ma lignant villous growth was found growing over the left side of the prostate, the villi projecting an inch or more into the bladder These were removed with forceps and spoon and the base cauterized ery ensued without notable event, and for eight weeks the renal function seemed almost normal, then the former symptoms began again and steadily in-The growth finally entirely creased in severity filled the bladder and involved the abdominal wall, producing a small fistulous opening, and constituting a tumor which could be plainly outlined above the symphisis and though the rectum, apparently filling the Death occurred October 8 Only the glands in the immediate vicinity of the bladder were found to be carcinomatous and no secondary growths in other organs were discovered

DR ELBERT WING There is a point in regard to the exclusion of tuberculosis by the examination mentioned, that is perhaps of interest in this connection. A gentleman who served for two years as interne at Tubingen, told me that they had a case there which they thought was tuberculosis of the renal tract, and that they made between sixty and seventy very careful examinations of the sediment of the urine for the bacilli of tuberculosis, but found none. At the autopsy they found tubercular ulcers in the kidneys, both ureters, bladder and urethra

DR ELBERT WING exhibited a specimen from a

case of

IYPHOID FEVER

I have here some fresh pathological specimens obtained at the County Hospital to day. The first is a portion of the intestine of a man that died of typhoid fever. It shows the swelling and tumefaction of the glands very nicely. There are also a few ulcers. There is a point of interest about the case aside from the typhoid fever, which was the involvment of the respirations, averaging between 40 and 60, pulse 120, temperature 101°. When the case came to the post mortem table the lungs were found to be quite extensively cedematous.

DR WING also exhibited specimens of a case of CIRRHOSIS OF THE LIVER WITH MARKED ASCITES

The man had been tapped a number of times and finally died in the hospital from ædema of the lungs He also had a scrotal hernia, and in addition to that there was an hydrocele of the same side omentum was attached to the anterior surface of the sac perhaps two inches from the external ring, and throughout the omentum there are wide bands of connective tissue which have formed through chronic passive hyperæmia. All of the connective tissue about the liver was in a similar condition hydrocele was the size of a goose egg, and has been ıncısed The testicle is perhaps one-third smaller than one would expect to find it The organ of principal interest, however, is the liver All that need be said about the history of the case, is that the man enjoyed the sobriquet of "Champagne Charlie" It is as handsome a specimen of gin drinker's liver as one ever sees. One can see the little projecting islands of tissue, which are almost small enough to give the surface of the liver the appearance of granulation tissue By way of emphasis of the difference between this kind of cirrhosis and the so-called biliary cirrhosis, of which there is not as yet much definitely known by the profession at large, I have taken the trouble to bring some slides of this and of biliary cirrhosis They demonstrate very beautifully the difference in the way in which the connective tissue is distributed throughout the organs In diffuse cirrhosis it is peripheral to the lobule, and surrounds nearly all of the lobules in any given field, but the connective tissue in biliary cirrhosis shows itself first around the gall ducts as little circumscribed islands clearly defined seem to be two forms of biliary cirrhosis, one with and one without hypertrophy of the liver former usually occurring as an acute disease in cases of hard drinkers

CINCINNATI MEDICAL SOCIETY

Stated Meeting, January 3, 1888

The President, C P Judkins, M D, in the Chair

DR RUFUS B HALL, of Chillicothe, Ohio, reported A CASE OF PYOSALPINA, WITH SPECIMENS

The specimens consisted of the right and left ovanes and tubes The left tube was dilated to the

size of a small orange which had contained pus The right tube was enlarged but contained no puru-There were shreds of tissue adhering lent matter to every part of the tubes and ovaries, showing plainly that they had been firmly adherent before removal The patient, Mrs C A, aged 41, had always been a strong healthy woman until after her third confinement, which occurred Dec 14, 1876, after which she had a severe attack of peritonitis After the subsidence of the peritonitis she continued to suffer severe pain in the left inguinal region which was so severe as to require the continuous use of morphia for three or four months She had menor rhagia which continued without interruption from the birth of her child until the following November. notwithstanding the fact that she was receiving treatment from her physician all that time. The treatment was continued without interruption until 1880 sensitive to pressure At that time she was totally disabled from overseeing her domestic duties on account of the pain in the left side, which had continued since the attack of peritonitis much worse for seven or eight days before each menstrual period The flow continued for ten days and was so excessive as to amount to severe flooding For two years previous to the operation she suffered much pain in the right ovarian region The pain was constant and growing worse with each recurrent menstrual period, this added to her already great suffering, and the dread that it would be as severe as that on the left side, so preyed upon her mind as to cause her to become despondent Intercourse was painful, and the pelvic pain was much increased for days after it By vaginal examination the uterus was found retroflexed and immovably fixed by adhesions To the left of the uterus there was a mass the size of a small orange that was excessively sensitive to pressure, there was also great tenderness to the right of the uterus but no lump could be detected by treatment, local and constitutional, without receiving any benefit She continued to suffer, and much of the time was confined to her bed, and was never one hour without the pain in her left side from the attack of peritonitis in 1876 until after the operation was performed

She was operated upon Nov 16, 1887 The pelvic organs were so matted and glued together as to re quire much force to separate the adhesions pyosalpinx burst and spilled its contents into the abdominal cavity The uterus was liberated from the old adhesions in the cul de sac, and a glass drainage tube inserted On the third day after the operation the temperature reached 100 5°, the highest Patient was permitted to leave her bed on the eighteenth day, and to go home on the twentyseventh, entirely relieved of her pain The uterus occupied the normal position in the pelvis and was as movable as that of a healthy woman She recovered without a bad symptom

The case has many points of interest connected with its history

I That in all cases of pelvic pain coming on after puerperal or gonorrheal inflammation which remains for months after the acute inflammation has subsided, and where it is clear that the cause of the pain is not located in the uterus itself, we are to suspect salpingitis and local treatment utterly fails to effect a cure

2 The retroflexion is a natural result following the repeated attacks of inflammation and cannot be cured by any local applications made to the uterus. The use of pessaries aggravate the pelvic pain and are dangerous, as likely to produce an acute attack of peritonitis that may cause the death of the patient

notwithstanding the fact that she was receiving treatment from her physician all that time. The treatment was continued without interruption until 1880 Finding that the pain remained the same in spite of all treatment it was discontinued until 1883, when she consulted Dr O C Andre, of Piketon, Ohio He found the uterus retroflexed and fixed, and very sensitive to pressure. At that time she was totally disabled from overseeing her domestic duties on account of the pain in the left side, which had continued since the attack of peritonits. The pain was

DR C A L REED said I am induced to say something on this paper, although I may state in advance that criticism must exhaust itself in commendation The history of the case shows that it went for eleven years without a proper diagnosis being made This fact illustrates a deplorable state of affairs so far as the general profession is concerned, and I cannot refrain from presenting the indictment, that physicians are as a rule too indifferent to the diagnostic points of tubal disease These cases are not hard to diagnose, and there are but few physicians who could not diagnose them if they would But the rule is, as illustrated by this case, these patients go along for years, to come finally to the surgeon's table for an operation that has become seriously complicated through delay

right of the uterus but no lump could be detected by vaginal touch. She had submitted to all manner of treatment, local and constitutional, without receiving any benefit. She continued to suffer, and much of in hopes of improvement.

DR REED thought it would have been better practice to have operated early, before the complications had developed. It may be laid down as a rule, that cases of pyosalpinx should be operated upon so soon as the diagnosis could be made, for experience has taught that there is no other way of affording relief. Mr Lawson Tait said that while assistant to Simpson, he saw many cases that were diagnosed as uterine displacements that he now believes were cases of pyosalpinx

DR OLIVER said that there was one point in the history of the case that impressed him very strongly, and that was the fact that although this woman had suffered intense pain for a period of eleven years, during which time she had practically been bed ridden, yet her nutrition was not impaired, nor did her general health suffer to any extent. This was evidenced by the fact that her weight at the time of the

operation was about the same as when in good claims by analogy that as the action of alkaloids is This well illustrates the idea that the Fallopian tubes are not of very much importance, physiologically speaking, pathologically they seem to be of considerable importance, so far as the woman's comfort and piece of mind are concerned asked whether it would have been advisable to operate upon this case early in its course

DR HALL said, in reply to Dr Oliver's question, that he would operate just so soon as he was able to diagnose a distended tube, and that he was indifferent from their physiological action. He refers to Nencki to the cause of such distension The treatment would be the same no matter whether it was hæmato-, hydro-, or pyosalpina

GERMAN MEDICAL SOCIETY OF PHILA-DELPHIA

Stated Meeting, December 12, 1887 THE PRESIDENT IN THE CHAIR DR LAWRENCE WOLFF read a paper on **PTOMAINES**

He first referred to the long known toxic effects of decaying cadavers, but how their toxic effect was attributed to a poison rather than the transmission of a special micro-organism creating a poison in the new soil He quotes the work of Pasteur and others and their effects upon medicine He argues for the spe cific action of the microbe from the fact that albuminoids can be preserved indefinitely if protected from them, reasoning that the organized body after death does not bear within itself the means of destruction or decomposition He states that other basic substances generated during life, such as the vegetable alkaloids, have great similarity with the cadaveric bases developing through the influence of bacteria, dwelling on the definite relations neces sary between agency and soil to develop certain He considers the action of bacteria a chemical one, in consequence of which the com plex molecule is split up into simpler ones admits the albumenoids, or rather parts thereof at the necessary pabulum of the microbe but denies the excretory character of the ptomaine, which he holds to be simply by products of the decomposition He quotes at length the history and development of our knowledge of the ptomaines, accords to Dupre and Bence Jones the priority of the discovery in the ani-Sonnenchem and Sulzer next promal chinoidine duced ptomaines resembling atropine and hyoscyamine, while Rorcsh and Fassender next separated a base giving some digitalin reactions Schwanert also He then reaches the labors of isolated a ptomaine Francesco Selmi and his work in various poison cases Liebermann next furnished a comine like ptomaine as did Brouardel and Boutmy who claimed for the pto maines the general reaction of reducing potassium ferri cyanide, which was soon proven fallacious After well known poisonous exhalations of ammoniacal to the consideration of pathological ptomaines He ptomaines will be found in the pulmonary exhalations,

proportionate to their chemical structure, so ptomaines must be, and as special micro organisms produce specific bases, he argues that the type and course of infectious diseases could in this way be explained Thus, he says, pathology has fallen an heirloom to the chemist as predicted by the late Austin He lays stress on the physiological expenments with ptomaines and contends, once the specific poisons of disease known, the antidote will arise as the first who furnished pure ptomaines, and then to the exhaustive labors of Brieger, the poisonous action of peptones shown by him and the consideration of the conditions favoring the development of Thus from lecithine Brieger claims choline, neurine and neuridine formed the development of a number of diamines called respectively cadaverine, putrescine and saprine, while mydæline he found the most poisonous and having mydriatic properties Brieger shows these to belong to the ethylene series and not to the pyridines and not responding to the reduction test. Villiers separated the cholera ptomaine from the intestines, of a trimethylomine odor acting on the nervous system and heart of animals He also isolated a pneumonia ptomaine which he holds identical with that of diphtheria The writer then quotes the labors of Gautter, who isolated parvoline and hydro collidine and others, as well as leukomaines from living tissues, and claims the classification of ptomaines with alkaloids, but thinks ptomaines destroyed in the body by oxydation, as not found in the urine Brieger in his latest researches describes as ptomaine a poisonous amidoacid, also midatoxine and methyl guanidine This investigator also experimented with pathogenic bacteria in cultures, and claims that while the staphylococcus pyogenes aureus produces only ammonium chloride the streptococcus produces besides this trimethylamine From cultures of the the typhus bacillus he ob tained thy photoxine, from tetanous ferment another giving physiological symptoms as the cultures author of the paper then quotes the tyrotoxicon of Vaughan and lays stress on its importance both as a He forensic ptomaine as well as one pathogenic of cholera infantum He then gives a resume of his paper, dwelling on the generally transient character of the ptomaines and their instability He speaks of the difficulty and complexity of their chemistry and calls attention to the danger of new productions in the process of isolation, but principally of the danger in his opinion of reducing their complex molecules into simpler ones during their purification He disclaims the relative value of their development from cultures and says their absence from the urine where alkaloids are found is no proof of their non existence or oxydation The principal point is in calling attention to the volatility of ptomaines in their basic state and the probability of their excretion by the respiratory apparatus, which is clinically borne out by the specific odor of diseases, and physiologically by the again referring to the vast labors of Selmi he proceeds compounds. He claims that the true pathological

and states that he is engaged on experiments with a view to test his theory

irritation quickly followed the ingestion of the food, but disappeared on the second day. On the ninth day, an attack simulating cerebro spinal fever ap peared with headache, vomiting, retraction of the neck, delirium, spastic contractions on irritation of all the voluntary muscles, acetonuria, and death by failure of respiration only hyperæmia of the cerebro spinal meninges Now, in considering this case, the primary gastrointestinal phenomena are readily understood to be those of local irritation nine days, do they speak for a late intoxication, or for an infection after a period of incubation? Is there any known ptomaine which introduced into the gas tro-intestinal canal would be so gradually absorbed, and so slowly eliminated, as to exhibit accumulative action at the end of so long a period?

DR FORMAD called attention to the fact that cadaveric poisons are volatile, so that the danger from dissecting wounds diminishes from day to day Virchow and von Recklinghausen ad- ing autopsy in all cases of infectious disease healthy tissue, as in sudden death from accident, or taken from the living animal, is highly poisonous if So too is the saliva, of introduced under the skin which the serpent virus is but a specialization

Another reason for delay, is the fact that the less dangerous bacteria of putrefaction will ultimately crowd out the specific bacteria of the disease confirms Dr Wolff's statement that oxygen is neces sary for the development of the bacteria-his investigations made in conjunction with Professor Vaughan upon the bacteria of diphtheria in milk, having illustrated this fact. In his opinion, bacteriology has as yet offered nothing absolute in the diagnosis of disease, except in the cases of anthrax, tubercu losis and relapsing fever, and he hopes that chemis try will, in the near future, give us the pathognomonic principles of disease

DR MAYS said It is not true that all animal poisons are the products of the development of microorganisms, and cited as instances the toxic effect of saliva, its analogue the serpent venom, and even the physiological peptones, when introduced under the skin So too papaitine, of vegetable origin, in which no bacteriological agency is claimed, is identical in its effect with the rattle snake poison Could not therefore certain cases of ptomaiæmia be due simply to the presence of physiological materials in the wrong place—as for example, the hydrated albuminoids in the circulation? The poi son in Dr Weed's case was probably the "Wurst Gift" of Brieger, analogous in its effects to curare

DR Wise called attention to the fact, that certain savage nations live almost exclusively on the meat of animals which died of a natural death, and whose meat is partially decayed-such as the nomadic Arabs and the Norwegian fisherman-without experiencing any ill effects

DR MILLER emphasized the element of susceptibility in the production of the phenomena of ptomaine DR WELD related a case of sausage poisoning, in poisoning, and cited cases, one of tyrotoxicon and which the well known symptom of gastro intestinal one of post mortem poison, in which only certain individuals experienced ill effects

> DR ROSENTHAL called attention to the fact, that in the cases of ergotized rye and fish pickle, vegetable and animal tissues furnish identical poisons, viz

propylamine and trymethylamine

DR SEILER in reply to Dr Wise, said that im-The post mortem revealed munity results from the habitual introduction of toxic elements into the system, as in the case of the poison of insects He questioned whether the endemic leprosy among the Norwegian fisherman, might not But those appearing after be, in part, due to the very habit cited

DR Collins expressed his belief that ptomaines are constantly produced in the body, and that autoinfection is prevented by the simultaneous produc-

tion of antagonistic ones

DR Wolff in closing the discussion, said that in Dr Weed's case the primary phenomena were due to direct irritation, while the later symptoms were of bacterial origin There is a remarkable resemblance between ptomaiæmia and curare poison-As we are ignorant of the mode of preparing vise waiting until the third or fourth day with the this drug, who knows but what decayed animal tissue may be one of its ingredients? In reply to Dr Wise's remarks, he called attention to the fact, that cooking decayed meat, would drive off the volatile ptomaines, and kill the bacteria, and that when such food is taken raw, the process of digestion effects the same result

FOREIGN CORRESPONDENCE

LETTER FROM VIENNA (FROM OUR OWN CORRESPONDENT)

Phosphate of Lime in Laryngeal Tuberculosis-Sublimate Fossil meal in Abdominal Actinomycosis Hominis-Syphilitic Myositis-Cocaine in Ophthalmic Surgery-Professor von Langer

In two of the recent numbers of the Internationale Klinische Rundschen, Prof John Schnitzler gives some interesting details of a lecture on the treatment of tuberculosis of the larynx with the phosphate of lime, which he had delivered in the Section of Laryngology and Rhinology of the sixtieth meeting of German scientists and physicians at Wiesbaden availed himself of the acid solution of the phosphate of lime, as recommended by Drs Freund and Kolischer, of Vienna, but later on he used phosphoric acid in different degrees of concentration, and at last, the pure and non diluted acid was used the solution of Freund and Kolischer by means of the brush or the syringe, and proceeded quite in the same way when he availed himself of the pure phosphoric acid The patients stated that they had a burning and prickly sensation after the application, which varied according to the intensity of the brushings or the injections. In some cases severe pains supervened, and sometimes also spasms of the rima

glottidis were produced On the laryngoscopical examination an increased hyperæmia of the respective mucous membrane was observed, and only on energetic application a grey-white scurf could be noticed which, in most of cases, soon disappeared In superficial, and occasionally also in deep ulcerations, these became cleaned in this course of treatment, and sometimes also fresh granulations were observed, which led to a temporary recovery, no permanent cure or that of a long duration could, however, be obtained in this way The same was also true of the treatment with gauze which had been saturated with the solution of the phosphate of lime

Prof Schnitzler then changed the method under consideration in such a way that he availed himself of the phosphate of lime in the form of a powder, instead of the solution which had been recommended The idea which led the lecturer to by Dr Kolischer adopt this procedure was the fact that powders which had not at all any antiseptic or specific quality never theless favorably influenced the ulcerative process by forming a protecting layer on the ulcerations, and this so much the more when, owing to their chemical composition, they have the quality of diminishing the secretion, a quality which was always stated as being characteristic for the lime preparations way in which the powder of the phosphate of lime Before the powder is was used was the following applied to the larynx the mucous membrane must be washed, and the erosions and ulcerations must be cleaned, the adhering muco purulent layers being re For this purpose the inhalations of chloride of potassium and chloride of sodium, as well as the solutions of salicylic and boracic acid, can be most advantageously availed of The inflations with the powder of the phosphate of lime are then made, and in such a way that the whole mucous membrane, and especially the diseased parts of the larynx, are quite covered with the powder After it had become evident that in this way of the administration of the phosphate of lime the secretion not only diminished form of spasmodic muscular contractions even when and the swelling decreased, but that also a tendency towards recovery of the ulcerations could be noticed, also other remedies which might exert a good influence on the laryngeal phthisis were added to the phosphate of lime, and after repeated trials, the following formula of a powder which had been used in numerous cases with good success was attained

Cocami mur o 2 (grams) Calcı phosphor 100 gtts v Ol menth piper

The results that had been obtained with the inflations with this powder consisted, first, in a cool sensation in the throat, a diminution in the irritability and a decrease in the pains, when the treatment was continued for a longer time, a diminution in the se cretion and a decrease in the swelling of the mucous membrane, and finally-at last in some cases in which the process had not much advanced—an evident tendency towards recovery could be noticed

Prof Schnitzler remarks at the end of his communication that, in spite of these not very considerable results, he would nevertheless recommend the use of ning of the process, much changed in their appearthe phosphate of lime in the now mentioned way ance, whereas the interstitual connective tissue con-

Though this remedy had no specific influence on the tubercular process, relief and, under favorable conditions, also recovery was obtained in several cases, and at any case this was an excellent remedy in all catarrhal affections of the upper air passages

At a recent meeting of the Imperial Royal Society of Physicians of this city, Dr Ullman, Prof Albert's assistant, brought forward a case of abdominal actinomycosis which had been successfully treated in Prof Albert's clinic by means of the application of a dress of sublimate fossil meal (Sublimat Kieselguhr, a paste which is prepared with sublimate and silicious earth) The patient presented a solid tumor of a violet color in the right hypochondriac region, and on the examination of the patient at Prof Albert's clinic, one discovered a fistula in the abdominal region which went as far as the bladder, and from which pus discharged on pressure The microscopical examination of the pus proved the presence of the actinomycosis granules which were characteristic of the disease under consideration The diagnosis of actinomycosis of the abdominal walls could already be made after the external appearance of the hypochondriac tumor, as such cases had already repeat-After convenient edly been observed at that clinic operation, a dress of sublimate fossil-meal (containing 10 per mille sublimate) was applied to the wound, and the patient could be dismissed from the hospital as cured after four weeks As to the conditions of the pus in cases of actinomycosis, Dr Ullmann remarked that, on repeated examinations, he had also met with other microorganisms, such as "staphylococci" and "streptococci," and he was of the opinion that the suppurating process was caused by these fungi, and that the actinomycetes created only a locus minor is resistentia

Prof Neumann recently communicated to the same Society some valuable details concerning myositis syphilitica He inquired into the cause of those intense pains in the rectum which supervened in the the rectal mucous membrane which had before been affected with syphilis was quite cured, and there was no longer any clinical symptom present which should The presence of explain these painful contractions "fissuræ" in the rectal mucous membrane could not serve as an explication of the appearances, as the tormenting pains still persisted when the fissuræ became covered with skin Taking into account the peculiarity of the pains in the rectum, which chiefly consisted in spasmodic contractions, Prof Neumann thought it necessary to examine also the sphincter anı externus and to find out whether there were not present pathological conditions also in this muscle, which should be able to explain the subjective symp-This was so much the more probable as it was known that, in gummous degenerations of the rectum, involuntary defecation took place owing to the fact that the sphincters have lost their normal function In cases of myositis it was chiefly the blood vessels of the perimysium from which the infiltration derived its origin, the muscular fibres were not, in the begintained many serpentine and dilated blood vessels with granulation cells. Soon after these appearances, the nuclei of the muscular fibres began to proliferate, and instead of one nucleus, from fixe to twelve nuclei lay close by each other in one series. Such a proliferation of the nuclei of the muscles could persist in slight inflammations of the muscles, according to the experiences of Recklinghausen, Billroth and Leube. The interstitial connective tissue filled itself more and more with granulation cells, the muscular fibres became thinner, and when the process was completed, the muscular substance was replaced by connective tissue.

The clinical symptoms were intense pains, especially during and after defecation, which in easy cases continued only for a short time after defecation, but in severe ones persisted for hours and even for days with the greatest intensity These pains became still more vehement when the myositis was combined with The syphilitic affections of the sphincter muscle were more painful than those in other mus cles, and they were also the most frequent ones The myositis syphilitica was observed at the clinic of the lecturer three times in all other muscles except the sphincter, in an interval of five years, whereas in a much shorter time, since Prof Neumann had begun to give a greater attention to this affection, it was ob served to occur five times in the sphincter muscles, and this in an interval of 11/2 year—the cases of gummous degeneration of the rectum being excluded The syphilitic inflammation of the sphincter was to be observed more commonly in women than in men, which could be explained by the fact that "papule" and "rhagadæ" in the anus were to be met with more frequently in the female sex than in the male one In future, even when all other symptoms of the syph ilis have disappeared, and only pains which are caused by the contractions of the sphincter muscle are present, we shall have to begin a general syphilitic treatment besides the local ones by remedies which facili-When the pains do not disappear tate resorption after this course of treatment, sphincterotomy will surely cure the patients In the tertiary stage of the syphilis, the appearances of paralysis with consecutive changes in the muscles were more striking, as the muscular substance of the periproctal connective tissue was destroyed, and strictures and involuntary defecations thus supervened

At a recent meeting of the "Verein deutscher Frzte" of Prague, Dr Herrenheiser delivered a lecture on his experience with cocaine as an anæs thetic in ophthalmic surgery, and stated, in the beginning of his communication, that when the subcutaneous injections were executed with a 10 per cent solution of cocaine, the anæsthesia was after the interval of a minute so complete that operation could be commenced As to the operations on the lens, he could only confirm the experiences of other In iridectomy, complete anæsthesia investigators was in most of cases present, and only in leucoma adherens, and especially in that after ulcus serpens, the patients had painful sensations, which Dr Herrenheiser explained by the strong traction which was

cocume was availed of in several hundred cases, the cocaine intoxication which was described by many authors, had at the clinic of Prof Sattler been observed only once This was a case in which o 04 grams (4 centigrams) of a 10 per cent solution were injected subcutaneously for the anæsthesia of the upper eyelid, and in which the operation was Dr Herrenheiser believed that it was rbandoned either the biosyncrasia against the remedy in question which gave origin to these symptoms, or that, owing to the late beginning of the operation, a too great quantity of cocaine was absorbed however, the operation was begun one minute after the injection, the greater part of the liquid emptied Losses of epithelium of the cornea were (flew off) very irequently observed, but in careful asepsis and antisepsis they were without any danger for the pa-The cocaine should either be prepared in an antiseptic fluid (in the clinic of Prof Sattler it is prepared in sublimate of a concentration of 10 10,000), or it should be heated to boiling before administra-Dimnesses of the eye, such as were first described by Bunge, have not been observed hitherto Thirty nine great operations on the eyelids were performed since the end of May, 1887, and in all the cocame proved very good

Seven enucleations of the eye, in which the injections were made under the conjunctiva (as far as possible behind the conjunctiva), were also quite painless. The statements that chemosis of the conjunctiva hindered the anæsthesia proved to be incorrect, and this was also true of the statement that the enucleation of eyes which had to be removed owing to intense pains was very painful to the patient when subjunctival injection of cocaine was resorted to

Charles v Langer, ordinary professor for normal anatomy at the Vienna Medical Faculty, died on the 8th of the current month in Vienna He was born in 1819 in German Bohemia, and made his preliminary studies at Pilsen in Bohemia, and studied medicine at Prague, where he obtained his diploma as Doctor in Medicine Langer was for a long time assistant to the distinguished anatomist, Prof Hyrtl, and in 1874 he was named ordinary professor for descriptive anatomy at the Vienna Medical Faculty He had a very good reputation as a teacher, and among his works, those on comparative anatomy, on the blood vessels, the joints, the growth of the heart, the anatomy and physiology of the skin, the mammary glands, deserve to be specially mentioned He was the recipient of several distinctions and was also knighted by the Emperor

DOMESTIC CORRESPONDENCE

LETTER FROM CINCINNATI (FROM OUR OWN CORRESPONDENT)

The University—Medical Colleges—Medical Socie ties—State Medical Laws—The Childrens Hospital —Typhoid Fever

renheiser explained by the strong traction which was A persistent and determined effort has been made executed for the detachment of the ins Though by the Board of Trustees to incorporate the various

institutions of learning under the banner of the Cin cinnati University This effort met with a great amount of strong opposition at first, so that for a time it seemed as though the enterprise would have to be abandoned, but at present the prospects of toms of typhoid, the majority differed very markedly ultimate success are very bright largely supported by the income derived from a bequest made in the will of the late Charles McMicken, a tax of one tenth of a mill is also levied upon the taxable property of Cincinnati for its support bequest of Charles McMicken amounted to upwards of seven hundred thousand dollars, this amount is almost entirely invested in real estate in and around Cincinnati In making their propositions to the educational institutes the Board asked for no abrogation of the rights and interests they enjoyed as pri vate corporations, but merely wished them to be come departments of the University, thus making the institution what it claimed to be-a University The Medical College of Ohio, the Miami Medical College, the Clinical and Pathological School of the Cincinnati Hospital, together with the Ohio Dental College and the College of Pharmacy, now consti tute the Medical Department The number of students in this branch of the University will aggregate five hundred, thus giving this particular branch no mean proportions when compared with the same department in the various other Universities of our country, and at the same time it will act as an incentive to labor for the union of the College of Music, the Art School, the Law School, and the other Schools with the University

The city has four Medical Societies in active op The Academy of Medicine, which is the largest and most flourishing one, the Cincinnati Medical Society, which is an off shoot from the above mentioned Society Walnut Hills, one of our populous and thriving suburbs, has a Society of its The Hamilton County Association of Physi cians is the newest arrival, in fact it has not passed The inefficient state of its first anniversary as yet our medical laws, together with the large amount of quackery, gave rise to the feeling that some steps should be taken to remedy these evils, and it was for the purpose of remedying these defects that this par ticular Society was organized, and strong efforts will be made this winter to efface some of these blotches from our State and city

During the past year an elegant Childrens' Hospital has been erected upon Mt Auburn, through the munificence of Messrs Thomas and Joseph Emery The government of the Hospital is vested in a Board of Directors appointed by the Episcopal Church, but the institution was given under the condition that neither sex, color or religion should be allowed to influence the admission of patients

Typhoid fever prevailed to an exceedingly great extent during the months of September, October and November, it being estimated that no less than three thousand cases occurred during these three it also bears a strong analogy to that form of disease months. The type of the disease was quite mild, that was designated "bilious remittent fever" by the consequently the mortality was small when com- older medical writers. In regard to the causation pared to that of previous epidemics The disease of the disease we can only call attention to several was not confined to any particular section of the attendant circumstances and allow the reader to

city, but was quite generally distributed over the entire territory, being found both on the hills and in the valley, and to about an equal extent While there were a few cases that presented the typical symp-The University is from the description ordinarily given of this disease, and in order to verify this assertion, I shall endeavor briefly to point out the most apparent points of dif-The stage of invasion was very short, in ference many cases apparently totally absent, there being none of the marked prodromes so common in enteric fever, thus giving an apparently abrupt inva-The temperature, instead of beginning mildly and slowly mounting up until it had reached its maximum, then slowly and gradually declining until a normal temperature was reached, would be very high (104°-105°) at the very inception of the disease, so that we often found that the highest fever occurred during the first two or three days, and that the course of the fever was very irregular and uncertain, sometimes reaching the normal standard in less than two weeks, and then again continuing for an almost indefinite period

In regard to the symptoms referable to special organs, we also find a wide divergence from these ordinarily present in typhoid Instead of the low muttering delirium we found in these cases an active, sometimes violent delirium, which in some cases would appear before the end of the first week and persist throughout the entire course of the disease Adynamia was less marked, sordes, bed sores and rose-spots were rendered conspicuous by their absence in the vast majority of cases Cephalalgia and backache were common, though ordinarily not severe Bronchitis and hypostatic congestion have not been marked features When we come to consider the abdominal symptoms we find the widest deviation from ordinary typhoid, constipation was the rule and diarrhoea the exception, tympanites was absent, or but slightly marked Tenderness and gurgling in the right iliac fossa was present, but with this there was a diffuse abdominal tenderness testinal hæmorrhages were more frequent than usual Quinia and other cinchoand uncommonly severe na salts were powerless to arrest the course of the Antifebrin and antipyrin were very exten sively used for their antipyretic action, and the results obtained were very good as a rule From this short résumé we are irresistibly drawn to the conclusion that although there were some points of resemblance to typhoid, yet the symptomatology was quite different from that disease in many particulars

What is the nature of this affection? Is this the simple typhoid fever, or is it a combination of typhoid with some other malady? In all those cases in which an autopsy could be obtained ulceration of Peyer's patches was found, in some cases the ulceration was very extensive. This epidemic is certainly very suggestive of Woodward's typho malarial fever,

draw his own conclusions Our supply of drinking water is obtained from the Ohio river, at a point contents into the river, and there are three or four more that empty a short distance below the water-The river has been lower this season than for several years past Another possible factor in the causation of the disease may have been the extensive improvements that have taken place in our streets the past year. All of our principal streets have been torn up and repaved, and the turning up have been an etiological factor

That neither the water supply nor the repaying of) the streets is the sole cause is proven by the occur rence of many cases in the outlying districts, where it they rely exclusively upon springs, wells or cisterns for their water supply One family, who relied en tirely upon spring water, were all (five people) pros trated by the disease There had been no other case in the neighborhood prior to the time of their attack

The majority of our people boiled their drinkingwater previous to its use, but, so far as discernable, with little or no effect upon limiting the spread of It was impossible to trace the course the disease of the epidemic, as we are never free from cases of typhoid, and these cases appeared to develop almost simultaneously in every district of the city this disease, and it appears to be true as regards all the infectious diseases, that there were more cases, and the disease persisted for a greater length of time, in the poorly sewered districts than in those that were well supplied in that respect

MEDICAL LEGISLATION

Dear Sir -The several editorials that have ap peared in The Journal recently, relative to legislative interference in medicine are terse and eminently correct The question, however, immediately arises How can it be accomplished?

Here in the Peninsular State, where schools are free and education is fairly forced into the masses by law, where we have a university second to none in and knowledge becomes stale, our legislators are impotent when a bill to protect the people from quackery is presented to them Canada and the surrounding States have, to a certain extent, forced charlatanism out of their limits by legislative enactment, but we stand here like Bartholdi's Statue of We are enlightening the World but there DOSE OF CORROSIVE SUBLIMATE FOR CHIL-Liberty is a horde of vampires that have crawled in from other States, besides many of our own, that we foster, which bask in the sunlight of our intelligent toleration and air their ignorance at the base of the statue

Lawyers that deal with the people's wealth, den-

save the mark-as a "doctor" "I'd rather be a dog and bay at the moon" than practice 'mongst a set of near the eastern extremity of the city, above this knaves and charlatans, but yet I've done so for thirty point there are several sewers that empty their filthy years and more, and still survive—as likewise do the quacks

In the year 1869 I had the honor, or indiscretion, -whichever you may choose to call it—of introducing the first bill in the Michigan Legislature to "Regulate the Practice of Medicine" That was the title of the bill It was a slightly altered transcript of the Ohio law then in force It was very mild it called for was a board of examiners, to be appointof so much soil in the midst of the city may possibly ed by the Governor, to attest to the applicant's qual ifications in the fundamentals of medicine What do you suppose those wiseacres did with it? They tossed it up and threw words at it They amended They amended it repeatedly The miscreants got so many amendments in finally that they crowded out the body of the bill, and there wasn't enough lest to hold an inquest on Then they sat down on it, and one of those old supervisors—such as adorn our legislature—told me that "death follows in the wake of you graduates "

It is easy enough, therefore, to infer that our high education does not necessarily contribute to the public weal, for Georgia, North Carolina, and other Southern States, where ignorance is supposed to be the rule and education the exception, have for years

prohibited quackery by law

"A little learning is a dangerous thing," and our One prominent fact has been observed in relation to legislators in the main have got the requisite amount to make them an object of fear Still, although my bill and I were fearfully mangled at the time spoken of, I believe that public opinion is becoming gradually educated up to a point where people can see that honorable members of the profession are working for their interests, and not from any mercenary motive

If the profession throughout the land would see to it that their representatives in the legislature were not in collusion with charlatans, and would post them relative to the importance of legislative action -and especially correct action-before it is everlastingly too late, our case is not entirely hopeless The apathy of physicians has been the bane of the profession in this respect, and I presume to say it will continue to be so until "doctors" overrun the land like the frogs of Egypt Still, notwithstanding the large and the World, perhaps, where learning runs rampant increasing output of graduates from our multiplying colleges, the probability is that if simple graduation from a reputable school were the only standard of admission to practice, the field would not be crowded, provided all others were excluded

MICHIGAN

DREN A CORRECTION

Dear Sir -In the report published in The Jour-NAL, of my paper on diphtheria, recently read before the New York County Medical Association, occurs the following "Dr Smith thought that the quantists that tamper with their teeth, and druggists that tity of bichloride that could be safely administered dispense their pills, all are under control of law, but to children of various ages was about as follows To the man that deals with their lives may be anything or a child of 2 years, 1/6 grain, 4 years, 1/4 grain, 6 nothing, only so he has registered himself—Heaven years, 1/2 grain, 10 years, 1/2 grain " The latter

sentence as it stands might do much harm, since diphtheria is so prevalent that physicians are anx 10usly inquiring how it shall be treated, and the sublimate in an over dose may be more fatal than the disease for which it is prescribed What I did say was that I thought that the above were about the quantities that should be given in divided doses, in ordinary cases, in twenty four hours, and I repeated this with emphasis, in order that there should be no Permit me also to correct another error relating to statistics of the treatment of diphtheria, which is going the rounds of the medical press Dr Lunin, of St Petersburgh, made comparative trial of various remedies in the treatment of diphtheria in the Oldenberg Hospital, with the following result Cases, 296 Percentage of deaths, 55

Fibrinous Form	Septic Phlegmonous Form	General Result
By turpentine, 8 30 per ct By resorcine, 20 00 " By sublimate, 30 20 " By chinoline 31 60 " By fer perchlor 32 60 " By bromine, 46 7 "	By turpentine, 81 00 per ct. By resorcine, 89 5 "By sublimate, 92 5 "By chinoline roo "By ferri perchlor 76 5 "By bromine, 88 9 "	Deaths 43 4 per ct 65 " 45 " 53 " 69 7 "

In some of the medical journals of largest circulation the table of general or total percentage of deaths is substituted for table of percentage of deaths in the septic phlegmonous form, the correct table of the result of treatment in the septic phlegmonous cases being omitted As Dr Lunin resides so far away he probably will not be aware of the mistake which translators have made His use of the sublimate was only local, and hence his statistics as regards this agent are not very valuable

Yours truly, J LEWIS SMITH, M D 64 W 56th St, New York, Jan 19, 1888

NECROLOGY.

JOSEPH O WEST, M D

Dr West was born in Barnstead, N H, June 21, 1823, and died January 28, 1887 When quite young he came to Lowell, Mass, with his mother fitted for college at the high school, and graduated from Dartmouth in 1845 He immediately entered the office of Dr Nathan Allen, of Lowell, as a student Having attended lectures at Harvard Medical School, he graduated from that institution Dr West soon afterwards settled in the town of Princeton, Worcester county, Mass, where he continued his professional duties until his death By education, genial manners, quick observation and a thorough knowledge of human nature, he was ad-Dr Thomas N mirably fitted for medical practice Gage, of Worcester, who as a neighboring physician had long known Dr West, bears this testimony

"To great natural abilities, trained, disciplined, and educated in the schools, he added high profes sional attainments, and the richer graces of a pure And such natural enand consistent Christian life dowments and acquirements, an intelligent and discerning people were not slow to recognize and appreciate Thus it came about that early in his life,

and to the end, he was respected, trusted, honored, and beloved, as it falls to the lot of very few to be Both profession and laity gave him, without reserve, their confidence and regard As a physician he was remarkably modest and unpretending, yet judicious and skilful, and equal to any emergency High pro fessional attainments and skill, and the wisdom gained by experience, he held as sacred trusts, to be administered under a sense of great accountability, and he was faithful to the solemn charge "

He was a member of the American Medical Asso-

ciation since 1865

His death was caused by acute laryngitis, followed by typhoid pneumonia and nephritis He leaves a widow (whose maiden name was Ellen M Gregory, of Princeton), with four daughters

ASSOCIATION ITEMS.

THE ANNUAL MEETING —We learn from the Chairman of the Committee of Arrangements for the next meeting, that the famous Cincinnati Music Hall has been secured for the general sessions of the Association and that all the Sections will be accommodated with rooms in the same building The members are to be congratulated that such excellent and convenient arrangements for places of meeting have been secured

The Committee of Arrangements and its various sub committees are fully organized and are working energetically to make the approaching meeting in every way attractive and successful Reduced railroad fares have already been secured Details in regard to them will be given later

MISCELLANEOUS.

THE OHIO STATE SANITARY ASSOCIATION will hold its fifth annual meeting, at Toledo, Ohio, Febuary 9 and 10, 1888 The meetings will be held in the G. A. R. Hall, corner of Adams and Ontario Sts, commencing at 8 30 AM, of the 9th, with a full programme of papers and important topics for discussion President, Professor E T Nelson, Delaware, Secretary, R Harvey Reed, M D, Mansfield, Ohio

ROLL OF MEMBERS CORRECTIONS —The residence of R F Henry, M D, Princeville, Indiana, in the list of permanent members in The Journal for December 31, 1887, should have been Princeville, Illinois Also for E P Dunning, Paw Paw, Michigan, read E B Dunning etc For Hall, Calvin C, read Halsey, Calvin C, Montrose, Pa

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE WEEK ENDING JANUARY

Surgeon C B Goldsborough, to proceed with insane seaman from Chicago to Government Hospital for the Insane January 16, 1888

Asst Surgeon F C Heath, to proceed to Buffalo, N Y, for temporary duty January 21, 1888 ¹
Surgeon G W Storer, to proceed to Wilmington, N C, Georgetown and Charleston, S C, Savannah and Brunswick, Ga., Fernandina, Jacksonville and Pensacola, F¹a, as inspector. December 20, 1887 December 30, 1887

ORIGINAL ARTICLES.

A CASE OF PEMPHIGUS OF THE CONJUNCTIVA. WITH REMARKS

Read in Section on Ophthalmology and Otology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY ROBERT TILLEY, M D

OF CHICACO

The case that I present for inspection is happily You see a boy of 12 years abnot a common one solutely blind He can simply distinguish night from day, and as he is certainly beyond operative relief, he may with scientific accuracy be termed blind He is blind, however, not from any disorder of the optic nerve, not from any central lesion, not from any affection of the uveal tract, not from any primary affection of the lens or cornea, not from any traumatism, but from a complete closure of both upper and lower conjunctival cul de sacs, and a com plete adhesion of both lids to the eye balls, the adhesion having taken place with the lids nearly wide

He was in practically the same condition in the early part of the year 1882, when I first saw him, as he is now, only at that time there was a large amount of photophobia and a certain amount of acute swelling of the borders of the lids, and there was a good deal more evidence of the existence of corneal tissue There was at that time practically no difference in the two eyes The left had slightly the most unpromising appearance I say he was practi cally in the same condition, I mean, of course, relative to his eyes There were at that time numerous bullæ over the body and one in the buccal cavity on the left side, on the cheek, and an angry vaccination pustule about an inch in diameter on the left arm These bullæ continued to appear at intervals over the body for about four years There has not been any appearance of them, according to the statement of the mother, for the last year All traces of them have disappeared except two almost symmetrically located on the two sides of the chest, where suppurfor yourselves

and from that time his eyes became inflamed so that in a brief period "they were as red as raw beef" The vaccination occurred in February, 1881, and the mother is confident that the boy has not been able to see since the month of April, 1881 Previous to the vaccination the mother is confident that there had been no affection of the boy's eyes whatever I mention this history particularly, because of its relation to a quotation by McCall Anderson from Sir Erasmus Wilson, which I shall make later

It was to relieve this severe redness of the eyes and closure of the lids that the child was taken to an eminent oculist of this city about the month of April, 1881 I am unable to describe the condition of the eyes at this time but I learn that the attendance was limited to about three or four visits

The interesting feature of this case is the evidence of healthy eyes prior to February, 1881, the appearance of redness and swelling and, according to the mother, inability to see since April, 1881, and my own personal observation of this hopelessly blind condition in the month of January, 1882 tainly within a year, and in all probability, the whole difficulty having occurred in two months the presence of bullæ on the body developed after the destructive closure of the lids, their appearance in successive crops for a period of four years disappearance of all traces of these bullæ excepting two which ulcerated on the chest, and I think I may add, the absence of any evidences of any inherited constitutional trouble I will add here that none of the other children were affected in any similar way

Are we then justified from these facts, together with the present condition of the eyes which you can inspect for yourselves, and which will be described more minutely later, in concluding that during that period of severe redness and inflammation the bullæ of pemphigus invaded so extensively the conjunctiva as to destroy its texture completely and cause this complete adherence of the lids to the eyeballs other words, that this is a genuine case of that rare affection, pemphigus of the conjunctiva, of an unusually severe type

You will observe that the time of development of ation evidently occurred These you can inspect the disease to such a disastrous result was very short and that there is no evidence of any previous tra-The history obtained from the parents is that all choma This I consider strong evidence of some dethe children were vaccinated at the same time, but structive agency, and in the absence of traumatism that the vaccine point which was about to be used of any kind, would be best explained by supposing for the patient was dropped, seized by a dog, and the existence of blebs with possibly slight suppurastill used That after the accumation fever occurred, tion destroying the thin and delicate conjunctiva

As you inspect him you will observe that the cornea of both eyes, if any cornea may be said to exist, are dry and horny That they are never moistened with tears or mucus of any kind You will see that the lashes are not much inverted, that the lids are completely adherent to the globes throughout their whole extent, and yet that the adhesion is so loose that it is evident that the pathological process has not invaded the deep tissues of the lids You will see that the punctæ lacrymalæ are obliterated, or at any rate not visible, that the palpebral fissure is of nearly normal length, that the distance between the lids in the centre is not far from normal, but that from the borders of the lids there extends over the eyeball a dry, horny pellicle, and that in the centre of the external surface of each eyeball is a dry small residue of a former tissue I have seen no evidence of the secretion of tears The movements of the eyeball are practically unimpeded I think you will fail to find any evidence from the contour of the face or the teeth of inherited trouble The teeth, however, are markedly irregular, but they cannot be referred to the classical teeth of Hutchinson When I saw him in 1882 this peculiarity of the teeth had, of course, not appeared, he was then about 6 or 7 years As you look at the teeth it would appear that the two upper central incisors are separated by a juries, he says "Sir Erasmus Wilson has recorded tooth of another kind

There is one thing that I must not fail to mention, and that is, that the mother has been and still is the subject of a contracted condition of the conjunctiva of the upper lids resulting in inverted ciliæ That is the only fact that seems to be of interest relative to the family history There are in all six children, with only one death

Early in the year 1882 I tried, assisted by Dr Gradle, and Dr Niles the family physician, to separate the lids from the ball of the left eye, but the result coincided with the experience of others—it There were no operative measures was a failure taken with the other eye

sults of a case of pemphigus, then it must be quite a unique case According to Pfluger, as quoted by W Lang, in the Transactions of the Ophthamological Society of the United Kingdom, 1886, Hebra had seen up to the year 1873, 200 cases of pemphigus, but in no case did it affect the conjunctiva course it may be said that patients so afflicted would | blebs on the mucous surfaces are very fugitive, and be more likely to visit the ophthalmologist than the from the delicate nature of the mucous membrane of dermatologist, but the cases are also exceedingly rare in ophthalmological literature The subject has on two occasions been brought before the Ophthalmological Society of the United Kingdom, and in the Transactions of the Society for 1886, Mr W Lang reviews the literature of the subject and says that up to that time only 23 cases had been published The first was published by Mr White Cooper, in the L O H Reports, July, 1858, and that only one of these twenty-three was published in America

In the Traité Complet d'Ophthalmologie, by De Wecker and Landolt, p 438, we read "Pemphigus even when universal only rarely affects the conjunctiva " Professor von Arlt, of Vienna, in his

"Diseases of the Anterior part of the Eyeball," as translated by Dr Lyman Ware, says "Conjunctival pemphigus is an exceedingly rare disease author has seen but two cases, and they had run their course" If a veteran of von Arlt's experience had only seen two cases there needs no other evidence of its rarity

Mr W Lang, in his report above referred to, presents three cases, two of which had already been presented to the Society under the title of "A Peculiar Affection of the Conjunctiva" Mr Lang strove to show that the cases published under the head of "Essential Shrinking of the Conjunctiva," by von-Graefe, and the syndesmitis degenerativa, of Stellwag, properly belong to the same affection and should be classified as pemphigus of the conjunctiva The subject, however, elicited much discussion and difference of opinion

In referring to the dematologists we find in Besnier's translation of Kaposi, p 57 "In pemphigus bulle have also been observed on the conjunctiva Pemphigus when it attacks the mucous membrane is sometimes confined to that membrane or precedes the lesion on the skin "

According to McCall Anderson, it seems to be occasionally called into activity as the result of intwo cases of this kind 1. A servant girl poisoned her hand with a red paste with which she was cleaning A few days afterwards a crop of bullæ intermingled with ecchymosed spots came out over the wrists and forearm and continued to trouble her for seven years The other case was one of a medical man who punctured his right hand Three or four weeks afterwards an eruption of bullæ made its appearance on his thigh and was repeated from time to The outbreak was pretime for eighteen months ceded by feverish symptoms, there was a scalded sensation in the skin and the next morning a fully developed bulla would be discovered"

I will not attempt to refer this case to its appropri-Assuming that we are justified in calling this the re- ate section as pemphigus vulgaris or pemphigus folia-I will leave that for the dermatologists

The special characteristics of bullæ on the con junctiva, if there are any, must also be left for those who have the privilege to observe them I can find practically no direct statement of a well observed All the writers on the subject say that such the conjunctiva and the constant friction of the parts, their character would be still more fugitive on I certainly saw one on the inside the conjunctiva It was about 3/4 of an inch long of the left cheek and 5% wide It was moderately distended, the edges terminated abruptly, there was no manifest inflammation around the edges, and it did not seem to give any serious inconvenience The contents were turbed as seen through the walls of the bleb

I have no evidence to offer as to the definite histo logical changes which occur in such cases I can

The question of diagnosis in its early stage, from

¹ McCall Anderson, 1887, p 255

the evidence at our disposal, must be difficult W Lang, in speaking of the one undisputed case that he presented to the Ophthalmological Society of the United Kingdom, confesses he had not recog nized it until Baumler directed his attention to it Landolt, in reporting a case, says it passed through the hands of Sichel senior, Liebreich unrecognized, and adds, that having had the opportunity of seeing the patient for several months he was convinced that the case was one of pemphigus Von Arlt says that one of the cases he refers to had been regarded as an obstinate manifestation of syphilis until it was recog nized by a dermatologist W Lang' says, in speaking of Steffins' case, "only once was a vesicle seen on the conjunctiva, and this occurred on the skin like shrunken lower conjunctival sac" Under these cir cumstances the diagnosis must be conceded to be difficult I have no suggestions to make

As to treatment little or no definite information can be offered, at any rate such as is based on pre I should say that any measures vious experience with which the surgeon is most familiar in the use of for the relief of an inflammatory condition of the mucous membrane, diluted so as to conform to the supersensitiveness of the eye, would be considered an appropriate treatment, taking as a criterion of applicability, that the treatment should leave the patient more comfortable, and that independent of any narcotic influence Of course if it were possi ble to anticipate any such disaster as this, any surgical measures having in view the absolute prevention of friction of the lids with the eyeball would be justifiable

I have said that my efforts to detach the lids after they were completely adherent to the eyeballs were fruitless, and I quote from Messrs Lang and Juler, to show that their experience was the same W Lang says * "Unfortunately, like some cases of pemphigus,"—he was speaking of cases otherwise classified-"it was not amenable to treatment, although every means, both medical and surgical, has been tried, such as transplanting a conjunctiva and other mucous membranes into the shrunken conjunctival sacs M Juler says in reference to one case "The house surgeon attempted to separate the lids from the globe by incision, and performed the operation of peritomy The operative interference' he adds, "was most pernicious" I have seen some of the transplantations of mucous membranes for kindred cases at different stages in its history, and although they appear well at first a few months is sufficient to destroy all enthusiasm associated with the hoped for success Of course this remark does not apply to transplantations for other affections

Type IN School Books—The Austrian Minister of Public Instruction has issued a decree forbidding the use in public schools of books printed in small type. Small type is bad enough, but what can be worse than small German type!

THE GERM-THEORY OF DISEASE AND ANTISEPTIC TREATMENT

Kead before the Keokuk County Medical Society, Dec 6, 1887 and published by special request of the Society

BY W T ECKLEY, MD,

It is not that I would add anything new to the already voluminous literature on bacteriology, that I call your attention to the germ theory of disease, but from a keen realization of the fact that so intimately interwoven with current medical and scientific literature are such terms as bacteria, incubator, desicator, serum media, culture-media, antisepsis, asepsis, listerism and serial cultivation, and such prodigious proportions has the new theory already attained during the past decade, that, when we consider the overwhelming evidence, both direct and circumstantial, in favor of the new theory, we are compelled, if we would read intelligently, to bring order out of chaos, and at least gain a well formulated idea of what is and what is not the germtheory, and what does and what does not constitute modern antiseptic treatment, medical, surgical, obstetrical and gynæcological

The greatness of the theory demands our attention and solicits our calm and unbiased judgment Cocaine is only awaiting the next revision of the pharmacopœia to become officinal and take her place in our materia medica with her elder officinal The germ theory of disease is only awaiting that slow popular acceptance that ever embarrasses the advent of discoveries In medicine, naturalism, empiricism, eclecticism, humoralism, fluidism, solidism, chemicism, mechanicism, stimulism, spiritualism, phlogisticism, pyrexism, vitalism, neuro pathology and physiological therapeutics, have all undergone the same searching scrutiny that the germ theory is undergoing to day Never were the blue depths of space more carefully studied by the telescope than are the tiny microorganisms of air to day studied by the microscope Never did Columbus look more keenly across the waves of the Atlantic for the Indies. than did Pasteui and Tyndal traverse the field of the microscope for those infinitesimals that cause fermentation in wine, breed discontent in open wounds, or evoke direful epidemics of splenic fever might add, never did clouds more portentous appear on the medical horizon, that threatened to engulf the whole theory and practice of the healing art, than those little nebulæ which a few years ago, originated across the sea, and now overspread the medical sky on two hemispheres

The nebular hypothesis would explain the genesis of the heavenly bodies, and nebulous masses, hitherto considered irresolvable, have been resolved by the Rosse telescope and their stellar identity demonstrated. The germ theory of disease would not, nay, in the nature of things could not, explain the genesis of the myriad microorganisms that fill sea and air with their ubiquitous presence, but vital phenomena formerly attributed to spontaneous generation, were resolved by the microscope, and simultaneously were added to Sylva's already opulent pos-

Oph Soc of the United Kingdom, Trans 1886 p 128

sessions, thousands and thousandsof micrococci and malariæ of malarial fever, the bacillus tuberculosis bacıllı

Having thus explained the aim of my paper, allow me to call your attention to the body of the argument under the following headings

r What is the germ theory of disease?

2 What is antiseptic treatment?

3 Wherein do these concern the general practitioner of medicine?

4 Wherein will the theory influence the practice of medicine?

The germ theory of disease is the doctrine of contagium vivum It centralizes in living, organic, vegetable, parasitic, microorganisms, of various proved that an infectious disease is due to a microgenera and species, the unique property of generating under favorable conditions, in organic beings, certain pathological and physiological processes Koch demonstrated in splenic fever a causative germ which he denominated bacillus anthracis, Klein a bacillus in typhoid fever, and quite recently Dr Pasteur demonstrated so called useful bacilli to which he attributed the following physiological char-No 1 Digests albumen No 2 Dis acteristics solves fibrine No 3 Dissolves gluten No 4 Co- former case " agulates milk No 5 Dissolves casein No 6 Transforms starch into sugar No 7 Changes lac-ling germs and the germ-theory from current medical tose to lactic acid No 8 Changes glucose to alcohol

According to the theory, these parasites constitute an ever-present legion whose individual functions are well specialized, although the votaries of their cause have not yet furnished a Linnaeus to classify their natural orders and formulate rules for the determination of their sex

As certain seeds sown in the warm zones yield the delicious fruits of the tropics, but sown where atmospheric and telluric conditions are unfavorable, perish by the wayside, so these vegetable germs, whose habitat is our atmospheric air, demand favorable environment for the reproduction and propagation of their species race—and the majority of which are harmless, generates phenomena of its own kind Just when and where the Adam bacillus came into existence, the germ theory no more explains than does the nebular hypothesis explain the origin of the "self-luminous substance diffused through space," which afterward became the starry universe. Here the world revealed by the microscope, and the million worlds re vealed by the telescope—strange and wonderful ex tremes—revert alike for the story of their birth to Holy writ

The nomenclature and classification of bacteria are imperfect in proportion to the darkness which Zoph distinguishes 1st, envolves bacteriology spherical, 2d, rod shaped, 3d, filamentous, and the general germ-theory was Dr Lister, who, thoroughly imbued name for germs, while the expression bacillus is used in a generic sense and applies to specific germs supposed to sustain a causative relation to certain pathological phenomena in the economy Thus the comma bacillus, according to Koch, is by him is to this day known as listerism in surgery pathognomonic of Asiatic cholera, the bacillus All antiseptic surgery is listerism, but not all listermalandriæ of glanders, the bacillus lyssæ of hydro- ism so-called is antiseptic surgery Listerism means phobia, the bacillus lepræ of leprosy, the bacillus absolute freedom from infectious germs

of tubercle

Micrococci are bacterial germs found in decomposition, and are very hairsplittingly differentiated from their bacillar brethren by bacteriologists, being classed as 1st, septic, 2d, zymotic, 3d, pathogenic, 4th, specific, and 5th, chromogenic Micrococci are considered causative in pneumonia, diphtheria, gonorrhæa, vaccinia and variola The specific nature of bacilli seems established, while micrococci are considered causative in suppuration and putrid processes

Dr Koch says "In no instance has it been organism, unless the microorganism in question is present, either in the blood or tissues of the animal affected with the disease, after death organism must be capable of cultivation in some suitable media outside of the body, and after being cultivated for several generations, must cause the same disease when introduced into the body of a healthy animal Finally, in the body of the last animal, the same parasites should be found as in the

I gather the following detached thoughts concern-"That the germ theory is now an esliterature tablished fact, that decay and putrefaction are due to living germs, that many species of germs are constantly present in the air, that disease germs are not generally present in the air, that these latter are prone to confine themselves to one locality, that they are carried from place to place by fomites, air and water, that disease geims multiply in contact with moisture, that some germs are indigenous to certain countries, that all the leading hospitals in the world have adopted the antiseptic practice, this being obligatory in the Prussian army and navy "

Here then we have spread out before us, in micro-Each germ—an ephemeral scopic proportions, the agents causative of many Bacillus and micrococcus, tenacihuman maladies ous of vitality, decimate society by typhoid fever, or scourge a trembling and panic stricken population Here the exanthemata bear with Asiatic cholera testimony to their presence, and there weeping mothers, rigid quarantine, prompt disinfection and newlymade graves, are silent witnesses to the late and awful visitation of micrococcus diphtheriæ

> The germ-theory was first announced by Pasteur, and unhesitatingly adopted by Lister and others In this theory were broad fields for therapeutic indications, and the development of these indications is radically changing the practice of the healing art in

all civilized and progressive Nations

with the idea that microorganisms, ever present in the air, and coming in contact with open wounds, cause suppuration and abscess, conceived the idea The practice instituted of an antiseptic dressing

section of the American Medical Association on "Wound Dressing" said "Such is the rate of progress, especially in the line of bicteriology, that surgical works published but five or ten years ago, are now considerably behind the times " He further adds—quoting from memory—"this is the bacterio logical era in medicine Probably the majority of the profession believe in antiseptic surgery, but none in listerism in extenso So well proven is antiseptic surgery say some, that a surgeon should be held liable at law for damages, if in the practice of surgery, where he had failed to use antisepsis his patient was not healed "

room be freed from disease germs, that operator and attendants be bathed, disinfected and clad in antiseptic garb, that hands of operator and as sistants be scrubbed in cor sub sol 1-1000, that the part to be operated upon be likewise treated, that all instruments be immersed in ac carb sol before operation that drainage tubes, bandages, protective, and ligatures be all antiseptically treated before operation, that the wound be antiseptically dressed

Concerning internal medicine, Dacosta expresses himself as follows "Thus far it must be confessed we have had, as regards internal medicine, no suc cess in the search after agents which destroy the The articles proposed are as apt to poison germs the patient as the microbe Some would be even more destructive, and none can be as directly and completely brought into contact with parasitic life in the organs or in the blood, as surgeons bring them in conduct in their antiseptic treatment of wounds But must we despair of conquering and injuries these germs? It is not too sanguine to anticipate that if their paramount importance be fully established, the means of their destruction will be found "

Dr Ellzey, on "Antiseptics in Medicine and Surg-"It is for the destruction of bacteria and their spores that we use antiseptics So long as we are dealing with refuse materials and substances outside the living body, we may use disinfectants in any stand the action of efficient germicides Man cannot withstand the toxic action of any known reliable germicide in germicidal strength Germicidal medicine, therefore, is beyond the possibilities of the We cannot kill bacteria or micrococci, still less can we kill the spores after they have gained access to the living body Our therapeutic measures must have reference to the possibility of rendering the fluids and tissues more or less unfavorable for the development of pathogenic bacteria. It is not possible to make of the fluids and tissues of a man's body a germicidal pickle until after the man is dead "

read you the following abstract from Garrigue's "An- labor is conducted in well managed lying in hospitals tiseptic Midwifery," on preventive measures in puer-

Dr Stubbs in his recent address to the surgical have a full bath at the beginning of labor, that enema of soap suds be given, that hands of obstetrician be thoroughly scrubbed in soap and water, and afterwards in cor sub sol, that hand and everything coming in contact with the genitals be previously immersed one minute in cor sub sol 1-2000 before touching the patient, that buttocks, thighs and vagina be washed and scrubbed with sol cor sub 1-2000, that no lubricant except carbolized glycerine 3 per cent be used, that in common cases the fingers be not introduced inside the os, that the presenting part, as it opens the vulva, be covered with compress wrung out of cor sub sol 1-2000, that the placenta be expressed by Antiseptic surgery provides that the operating Crede's method, that the vaginal cavity, after delivery, be injected with warm sol cor sub 1-2000. provided said cavity was at any time during or after delivery, entered by the hand, that uterine injections 1-4000 cor sub sol be given, provided this cavity were entered by hand or instrument, that patient be washed in 1-2000 cor sub sol, binder and antiseptic occlusion dressing applied, and same be changed three times daily in private practice, that genitals be flooded with cor sol after urination and defecation, that no vaginal injection be given in normal cases "

All these antiseptic precautions, whose foundation is the germ theory, and actually reduced to practice in some of the leading hospitals of the world, and endorsed by the leading spirits in medicine, surgery, obstetrics and gynecology, both in Europe and America, evidently mean much if they mean anything at Granted that antisepsis is more easily carried out in hospital than in private practice, does not the question arise are the beneficiaries of the former any more entitled to the beneficence of a treatment which, during the past decade, has reduced the mortality rate 60 per cent, than are the landed and intelligent element of the latter? In our large humanitarian charity hospitals we find only too often an inappreciative, would-be lawless congregation of society's choicest slums, sirens, embryonic dynamiters and revolutionists, cared for in palatial environment, amid all the regal splendor, appointment and antisepticism possible in the reach of American munifidegree of concentration necessary to secure their cence and modern science. This is all nice and efficiency, but within the living body, we are met by proper, perhaps, and certainly is the highest tribute the limitation of the power of the organism to with- to our free and charitable institutions, but do we find commensurate antisepticism thus efficiently carried out in private practice among the veritable fosterers of the aforesaid charity institutions? If not, why not?

From a medico legal standpoint, the practice founded on the germ-theory of disease continges the general practitioner's most vital interests, and the question arises are we longer justified in following the moderately successful beaten paths of the past, or shall we harmonize our treatment with the teachings of the germ theory? In the event of death from puerperal septicæmia, e g, would the shrewd prose-At the expense of your indulgence, allow me to cution ask-after having enlightened the jury on how

"Doctor, before assuming charge of the case, did peral infection It provides that the patient should you see that your person and clothing, and that of all your attendants (the 'granny women,' of course), were thoroughly bathed and scrubbed in soap and water, and afterward in a solution of cor sub of the strength of 1-2,000?" In nine cases out of ten the answer would be no

"Doctor, did you bathe the patient, and wash the abdomen, buttocks, thighs and external genitals in the antiseptic solution aforesaid?" In ninety-nine cases out of a hundred the answer would be no

"Doctor, before each digital examination did you immerse your hand in the solution cor sub and let it remain there for one minute?" How often would your answer be yes?

"Doctor, did you cover the presenting part on its emergence from the vulva with compresses of cor

sub?

"Doctor, after delivery, did you wash your patient in a solution of corrosive sublimate and apply an

"Now, doctor, you may describe the occlusion dressing to the Court and jury, and Prof Garrigues, our expert, will tell us whether he uses that kind of occlusion in the lying-in hospital of which he has by feet and inches, comprehending at most only a charge

"Now, doctor, is it not a fact that you went directly from Sam Smith's, where you were attending a case of phlegmonous erysipelas, and without changing your clothing or washing your hands made an examination of this woman, and told Susan Bangs The efficient artificial antiseptic you can use at pleashere that it was a malpresentation, and turning would probably be necessary?

"Doctor, do you recognize the erysipelatous contagium causative in the production of puerperal septicæmia? Prof Garrigues will enlighten the Court on this point "

These questions might be continued by hypothesis indefinitely to surgical cases, but for our purpose the point is fully developed, and at any rate the partu-rient canal furnishes all the conditions of an open wound, the one being as readily susceptible to infec-If from no other motive than a tion as the other self-conservative one, I argue that our only safety in medico-legal cases lies in rigid adherence to the principles of the germ theory, for then, and then only, will we be able to avoid the opprobrium and penalty which the majesty of the law attaches to the dual crime of omission and commission

Derogating from the concession made above for argument's sake-that antisepticism is more easily carried out in hospital than in private practice—I am convinced that the opposite lies within easy reach of each and every live practitioner in the country, and why? Because we, as a class of country practition ers, are surrounded by illimitable opportunities and advantages, as yet poorly developed, it is true, which are made possible in large general hospitals only by laborious detail which in itself divests the whole system of half its efficacy

Let us notice the modern typical general hospital -with its elegant appointments, magnificent operating rooms, water supply, efficient school for training nurses, long list of competent physicians and surgeons, spacious amphitheatres, hosts of trained nurses faithful in the discharge of every duty, pavil-

ions and wards, strict antiseptic regulations-in fine, its hospital perfection. No human work is perfect Did we consider its proximity to one of the greatest railroad centres of the world? Did we remember that only charity patients gain admission to its wards? Did we consider the physical depravity and moral degradation of 90 per cent of its intramural invalids? Did we consider the gonorrhoal, syphilitic, scorbutic. consumptive and exanthematic effluvia that necessarily contaminates the air from such a medley congre-

Divested of its superfluities, things that to it are necessities, but to the country practitioner superfluous, because here the necessity does not exist for battling against such hosts of pernicious germs, let the country physician carefully consider the analogous and essential points of difference between his quiet rural practice and that of his hospital contemporary, as foreshadowed in the preceding paragraph

In the first place, gentlemen, you are all house physicians to hospitals not hemmed in by circumscribed architecture, whose dimensions are estimated few acres of surface, and accommodating hundreds, but of hospitals miles in extent and composed of hundreds of pavilions, having few inmates, each patient separated from the others by miles of atmospheric oxygen, nature's most efficient antiseptic. The class you deal with is the elite of society contaminated by a few dregs Your water supply may always be first in quantity and quality

It is a mistaken idea that hospital practitioners enjoy an autocratic authority over their patients not attainable in private practice Your word must and will command both respect and obedience, other-You can enwise you cannot meet with success force cleanliness, and make quite efficient nurses from members of the family This must all be preceded by much toil on your part, but still it is pos-Remoteness from great commercial and manufacturing centres, fresh air, pure water, a minimum of diseased patients in one place, unadulterated food, and milk especially, are things ever in your favor, and with difficulty attainable in large general hospitals. In hospitals the nurses are educated up to a keen appreciation of antiseptic precautions, and the physician's high authority In the country these prerequisites do not come about spontaneously are creations of time, perseverance and popular edu-Let us see how this latter is brought about cation

An old adage says "Make haste slowly," and it indicates the only rational plan of procedure in engrafting on the minds of the masses the importance of antiseptic treatment Until this shall have been accomplished, the orderly antisepticism in our wellregulated hospitals must continue to show us a smaller mortality rate than we, with all our boasted pure air, unadulterated milk and farcical germicides The medium ground of antialone can accomplish septic perfection, then, lies between the "Slough of Despond" of the country practitioner, and the elevated plateaux of hospital practice

The presentation and demonstration of any new

theory to the masses is a task not easy of accom-In presenting the germ theory to the people, the laboriousness of the task must fall on the general practitioner The masses cling with wonderful tenacity to the traditions, superstitions and Herein is the charlatan's ideal doctrines of the past and most impregnable stronghold You can convict the murderer, punish the trespasser, imprison for grand larceny, rape and seduction, but where can you find remote provinces and territories an advocate nimble enough of tongue to shake in the popular mind that innate and implicit confidence every department of medicine which mankind in general place in the salves, embro cations, poultices and nostra of traditionary brilno more responsible therefor than are we for those features and idiosyncrasies which distinguish us as urethra man from man

Within the memory of you all, there occurred in a certain section of our country an epidemic of puer peral septicæmia, during a time when glanders was prevailing among the horses of the same locality Every parturient woman died at that time loving husbands day after day cared for their horses, with their suppurating submaxillaries, and also devoted time and attention to their parturient women have met the same opposition as now

I once attended a patient in a condition of chronic blood poisoning from the absorption of pus from a carious bone I suggested removal of the carious bone, and a thorough bath To the former he demurred on the ground that an old lady had told him "healing of such things would surely kill" Against the bath he urged the objection that thirty years ago, while yet in Germany, he had bathed, and as that made him sick he would never try the same expedi ent again

Even in the time of Shakespeare men were egotistic on medical topics, and the same mania is ludi crously present to day, even among people otherwise cultured Who has not been talked full of cancer issue with you on the rational treatment of fevers? Where is the divine who at some time of his career has not subscribed to the efficacy of some patent nostrum as potent as Lydia's or Warner's? Where is the teacher in our public schools who would say "call a physician," instead of "My grandmother learned from an Indian woman how to cure sore throat" Would an untutored boor presume to give you advice in adjudication? Granted the affirmative, would you institute proceedings on this fool's opinion before consulting a competent attorney? In the painful event of a monstrous carbuncle on your nose, would you not try everything from skunk oil rendered in full moon to turnip salve stirred three times with a forked stick, before consulting a competent physician?

Despair we need not, for analogy alone shows medicine to be not less progressive than her sister In polity the paternostic and communistic ideas of the old world have given place to fine and orderly systems of government In religion idols

culminated in gigantic educational systems, the wonder and admiration of the age Modern chemistry bears no facial resemblance to alchemy, her grand-The telegraph and telephone have made mother journalism a great popular educator Jurisprudence, a delicate exotic plant at the beginning of this century, having gained new strength on American soil, now sends the strong arm of the law into the most

Equally important advances have been made in Anæsthesia both local and general has wellnigh reached perfection, divesting formidable operations of all their pain and liancy? I believe we all have the infection, and are half their terror. In the hands of Neumann and others, electricity dissolves organic stricture of the The surgeon's knife invades the abdominal cavity, even the brain itself Opium, calomel, jalap, quinia, and a number of other drugs used by the older practitioners will stand the test of time, modern discoveries making their virtues more valuable and less questionable. The cold bath in typhoid The fever is destined to abandonment Antipyrin enjoys great popular favor

I would suggest that, as live and energetic practitioners in the country, we keep posted on the latest If the germ-theory had been advocated then it would scientific medical thought, and be ready to accept the truth at all times I consider it a duty we owe to our patrons and patients to give the sick the advantage of any hygienic regulation, any therapeutical agent, any meritorious medicament that may prolong life The people must be educated up to modern ideas of prevention of disease, care of health, and the value of scientific investigations Teach them that physicians understand the fullest details of physic as tradesmen understand their avocations Teach them that food, water and air may, under certain condi tions, be fertile sources of disease, solicit their cooperation in times of epidemics, gain their confidence, give them no time for grandmotherly lore, and I am sure they will respond with refreshing alacrity

Hastily reviewing the germ theory of disease, the cures? Where is the layman who would not take doctrine of contagium vivum, long ago enunciated by Pasteur and Tyndal and others, practically applied to surgery by Dr Lister, to obstetrics, gynecology and general medicine by hosts of careful observers in Europe and America, its principles gradually finding bold expression in the efficacy of its achievements, assuming an antiseptic garb it stands open to day to the keenest scientific criticism of the age tice in surgery has wonderfully reduced death rate from infectious germs, and the whole healing art is feeling the impact of the new treatment germs cause disease A thousand microscopes are identifying and classifying these germs, a thousand chemists are endeavoring to find agents capable of destroying these germs Quinia destroys the bacillus malariæ Corrosive sublimate effectually protects open wounds The final analysis of any new theory is made by the general practitioner Do not become discouraged by the wayside, but lend a helping hand to science

Leaving the present status of medicine, with all its have been dethroned and Christianity preached to the imperfect diagnostic and therapeutic resources-of heathen The "lickin' and larnin'" of the past has course ever grateful for whatever of ment and preci

sion in diagnosis and treatment we now possess-let us pass in hasty review those instruments which sep arate medicine into ancient and modern the clinical thermometer, the stethoscope, the ophthalmoscope, the laryngoscope, the nucroscope

The stethoscope makes possible wellnigh exactitude of diagnosis in cardiac and pulmonary disorders The clinical thermometer reduces fever to simplicity The ophthalmoscope places the theory of inflamma tion on an immutable basis The microscope, more than any other product of man's ingenuity, makes the etiology of disease both rational and scientific On it, and it alone, rises that vast superstructure of recent times—the germ theory of disease and anti-The physician of the future must septic treatment be as expert in the use of the microscope as is the physician of the present in the use of the stethoscope The microscope reveals new worlds to science Under its powerful lenses we behold a fertile field of micro scopic vegetation, wonderfully diverse in structure. yet eloquent enough to call forth Linnæus's spirit from the shades and demand for her multitudinous genera botanical classification

In the near future, when anatomy, chemistry and physiology shall have completed a few more biological revolutions, lingual inspection and radial palpation will be quite insufficient data for procedure against bacilli with quinia and calomel Our empiricism will elide into rationalism, and our present diagnostic crudities will remain on the therapeutic nomenclature of the future as ancient names preserve their heroic derivation Greater precision in diagnosticating disease will proportionately enhance prognosis therapeutics is as yet a thing of embryonic magnitude First must the whole field of empiric drugs be traversed in search of parasiticides These latter, to be available, must meet two vital requirements they must be innocuous to the fluids and solids of the body, second, they must devitalize germs and their spores or render the animal innocuous against their presence

THE HYGIENE OF PHTHISIS

A Paper read before the Philadelphia County Medical Society, January 11, 1888,

> BY LAWRENCE F FLICK, MD, OF PHILADELPHIA

For twenty-four hundred years, and probably during all preceding ages, some of the best minds the the world has ever produced have studied and coped with phthisis, and, in spite of the accumulated knowledge of all those years, about one-fifteenth of the human family falls a victim to it yearly There is not a clime in which it does not exist, nor a period of life in which it does not occur The rich and poor, the civilized and uncivilized, become its prey Since ket unless heavily endowed by purse or landed es it cannot be cured, it is but reasonable to try to prevent it, and much has been done in this direction What percentage of deaths during the last century

1 In 1880 the percentage of deaths from phthisis in the United States was 12,059 in every 100,000, and in England 9 141 in every 100 000 Taking these two countries as a basis we may assume that, the world over, about 7 per cent of the deaths are due to phthisis

was due to consumption in the days of Hippocrates cannot be known, but that it was large would appear from his words in speaking of a certain period, viz, that "consumption" was the most considerable of the diseases which then prevailed, and the only one which proved fatal to many persons " Writers upon the subject subsequent to Hippocrates are equally barren in statistics until about the seventeenth cen-The first figures that I have met with are in a foot note in Dr Bateman's Diseases of London, in which a Dr Heberden is quoted as saying "that' in 1669 the deaths from consumption were to the whole as one to about six and two tenths, in 1749 one to about five and five tenths, in 1799 one to about three and eight tenths, in 1808 one to about three and six tenths, and in 1818 one to about four and two tenths" In the beginning of the present century Dr Willan, in his statistics on the diseases of London, gives the percentage in his private practice as about one in three, and says that the proportion in the general mortality reports for the winter months at that time varied from one-third to one half 1880 the percentage of deaths from phthisis in England was 9,141 in every 100,000, which indicates a marked improvement This improvement is not due to a larger number of cures, but to a more successful prevention that follows in the wake of civilization

It is scarcely disputed by any one at the present day that consumption is due to the bacillus tubercu-Concomitant with this doctrine is necessarily that of its contagiousness, and whoever accepts the one must accept the other And why should it not be accepted? It is the reasonable doctrine, and one consistent with all modern teachings about dis-It is, moreover, the only doctrine that can explain all the phenomena of the disease without appealing to one's credulity, and upon the assumption of which we can ever hope to construct a barrier to the progress of the disease

Heredity ought to be out of the question at the present day It is an unreasonable theory, and at variance with all modern knowledge about the etiology of disease Its complete eradication from the public mind is one of the first steps necessary in a sanitary crusade against phthisis So long has it held sway, and so thoroughly has it been woven into our literature, into our ways of thinking, and even of acting, that it has actually become a remote cause of Men and nomen are daily dying victhe disease tims of consumption because they have not the courage to escape its clutches Their grandparents or parents, their uncles or aunts, or somebody in their families has died of the disease, and it is a foregone conclusion that some day, they will die of it too They are tabooed by society as fore ordained victims, they are refused life insurance on the slightest pretext, and are at a discount in the marriage mar-Their lives are one continuous worry lest the disease overtake them, and yet they do nothing to

avoid it, or the depressing influences which lead to

² Francis Adams' translation page 353 ³ Historical Survey of the Diseases of London, page 22 Thomas

If they do finally succumb to the disease, their matter in the blood in its production

Somewhat akin and often confounded with hered ity is the doctrine of predisposition That some families are more apt to develop certain diseases than others is beyond dispute. What this predispo blood, the nerves, or tissues, is as yet one of the hid den secrets of nature and reappear, or may disappear entirely. It some times goes with one or the other sex, and sometimes tion accompanies certain complexions and features Whilst it often exhausts itself by the laws of survival, it may also be generated de novo by the modes of died of consumption The tight lacing girl, life and habits of the parents the pale faced, dissipated young man, the overworked store girl and factory hand, the tea drinking, bibbling servant girl, the drunken father, the half starved, badly clothed mother—these are some of the progenitors of predispositions of phthisis

So much in brief about the theories on the etiology Their consideration has been neof consumption cessary in order to study intelligibly the means for

its prevention

Both in theory and practice we find that consumption, though contagious, is but mildly so This is, in my estimation, not so much due to the inefficiency of the bacillus tuberculosis as to the withstanding The bacıllus tupower of the lungs of most people berculosis never finds a nidus in a healthy lung—by healthy, I mean not only freedom from pathological change, but a strictly physiological condition in which every function is properly performed the brain, I believe the lungs may be functionally abnormal, and yet there be no pathological change discoverable There is a very close relationship between this functional abnormality of the lungs and the digestive apparatus, and, in a sequential way, the whole nutritive system It is upon the stomach. then, almost as much as upon the lungs, that much depends in the prevention of phthisis The stomach is usually the first traitor in the human economy Through its derangement many diseases gain entrance into the body. When the stomach fails to perform its work, the lungs will soon do the same lungs become a proper soil for the bacillus tubercu-Every care should therefore be taken to keep the stomach healthy, and to do this a sufficient and proper supply of food is necessary Too much food is as injurious as too little, and improper food worse in the power of everyone to avoid phthisis When the stomach is filled with indigestible food, nutrition is not only withheld, but the its work for some time thereafter

It is generally in overfed and improperly fed people that we have what is called galloping consumption Though apparently well nourished, their en

It is from this class of people education and that of the public have been factors that the mortality list from consumption is kept so high in America, and it is chiefly the foreign element in our population which constitutes the class deaths from consumption in the United States are nearly twice as numerous among the foreign population and their children as among the children of the sition consists in, and whether dependent upon the native born. In Rhode Island, according to the health reports of that State for 1880, one person in It is certain, however, that every 486 of native parentage dies of consumption, it can be transmitted for generations, and that, like while one in every 286 of foreign parentage dies of complexion and features, it may go to only certain the disease. According to the United States census members of a family, may skip a generation or two reports for 1880, out of every 1,000,000 deaths, 242,842 males and 302,046 females die of consump-This represents all nationalities and colors Among the colored race every million deaths repre sent 248,179 males and 326,973 females as having Among people of Irish pa rentage 309,507 males and 375,636 females die of consumption to every million deaths, and among people of German parentage the victims of the disease number 249,498 males and 254,958 females to every million deaths It will be seen that the largest percentage of deaths from the disease is among Irish immigrants and their children. This is usually ascribed to the change in climate Ireland has a much damper climate than America, and therefore one better suited to the development of phthisis real cause for the larger mortality from consumption among foreigners, and especially among the Irish, is the change in diet At home they have been accustomed to a plain, healthy diet, and when they come to this country they at once take to the varied heavy Where they have eaten little diet of Americans meat at home, they eat it in profusion here they have drank good milk and eaten vegetables at home, they drink teas and coffees and eat spiced foods here They soon become thorough Americans in their stomachs, and even outdo the natives The consequences are indigestion, malnutrition, tu-The German, though frequently pursuberculosis ing a similar course, is often spared by his characteristic thrift and economy He partakes more sparingly of the good things that come in his way, because of his anxiety to prepare for a rainy day His fondness for beer, a beverage that he manages to secure wherever he goes, may likewise have some influence in shielding him against phthisis

Sufficient fresh air, sufficient food, and sufficient A vicious circle is established, and they mutually rest and sleep are the watch dogs of health, and derange each other Malnutrition follows, and the where they are on the alert consumption can never Bacilli tuberculosis may permeate the air. but they can do no harm Could civilization reach such a stage of perfection as to make it possible for every human being to have all these, it would be condition of things is, however, impracticable therefore becomes necessary not only to deprive the stomach is unfitted for the proper performance of bacillus tuberculosis of its proper soil, but also to de-This function belongs as well to stroy the bacıllus the State as to the individual Modern governments are beginning to appreciate the importance of preserving the health of their people, and are every tire appearance is suggestive of too much foreign where establishing health boards. As yet, however,

they do not go far enough grown beyond the mere art of prescribing remedies, it has become a science of protecting man against For the present we must content ourselves with disdisease and enabling him to attain his three score As government exists for the good of so ciety, it ought to avail itself more extensively of so powerful a means to its end The medical profession should be represented in our government There should be a Department of Medicine, as there is a Department of Agriculture, of Justice, of Fi Surely human lives are as valuable as those of dumb brutes, and we want protection as much against the invisible foes which threaten our health as the visible ones which threaten our hearths Unfortunately, public sentiment has not yet been educated to appreciate sufficiently the importance and benefit of sanitary measures, to make such a thing practicable Did such a department exist, and did physicians in good standing and with scientific attainments occasionally enter the field of practical not confine it, nor afford protection politics, and allow themselves to be returned to city benefit that could be derived from it, would be the councils and State and National legislatures, sanitary science might shed its light upon legislation, and many existing hygienic evils be remedied, many and their protection against contamination by the social and commercial customs and practices which sputa are daily generating predispositions to consumption inhumanity of separating the poor victims for years by the thousands might be corrected Plainer living from their relatives would come through proper instruction upon the be attained without isolation by disinfection subject and the instillation of the necessary sentiment in our schools Not only ought children to be taught what to eat and drink, but also how to prepare their food and what quantity they can take con-Nor should instruction upon sistent with health the proper adaptation of food to the time of life be Many children are already dyspeptic when their school days begin, and in their cases the benefit of instruction could only accrue to the The depressing influences of second generation private vices in children and young people could latter carbolic acid of corrosive sublimate solution often be averted by early instruction of the proper Such instruction should, of course, come through the parents, but parents are themselves fre quently devoid of the proper knowledge, hence the government might supply it to them by the free distribution of appropriate books and moral evils might be warded off were the proper sults, however, would be ample compensation for knowledge brought to the thousands who would the inconvenience and expense That there would gladly avail themselves of it, were it within their be a marked decrease in the mortality from phthisis

against the oppression of the strong One needs but more reliable reports would be made and fuller visit the parts of large cities where the poor live, and note the crowded, filthy courts, alleys and tenement houses, or take a stroll through a badly ventilated mate proper knowledge upon the subject. If ignorfactory or retail store in which the employes are compelled to work long hours in unhealthy positions, and with the most wretched accommodations for the ordinary demands of nature, or examine some of the articles of food and drink that are openly sold in tions in which they must necessarily contamshops and on the streets, to understand what could mate the clothing, food, and drink of others be done in the way of sanitary science by wise legis-The remedying of such wrongs and oppressions would very much lessen the mortality from makers, consumptive bakers, consumptives indeed consumption by withdrawing the soil necessary for in every calling of life These people do not sus-

Medical science has its development But all this is mere speculation of what we may hope will take place in the future cussing the weapons against the bacillus tuberculosis, which governments can use as they are now constituted

The usual methods employed by our boards of health for combating disease are isolation and disin-Against consumption, isolation if it were even practicable, would be both useless and cruel It is a question in my mind whether the existence of the bacillus tuberculosis is solely for the destruction of human lungs! In view of the universality of phthisis, it is not entirely a matter of fancy to sup pose that the parasitic life of the bacillus in man is incidental, and that it plays some useful iole in the great chain of transition between organic and inorganic matter It seems to be everywhere and to be wasted about by the air Isolation could therefore The only withdrawal of the relatives of patients from an at mosphere saturated with the germs of the disease, This would be a poor return for the dreadful The same results can moreover well equipped thorough boards of health and properly instructed laity, satisfactory protection could be secured to those who by family ties or otherwise are compelled to live in the same house with the afflicted The house, and especially the room, in which the patient sleeps ought to be frequently disinfected with some suitable germicide, and particular care should be taken to disinfect the sputa former purpose sulphur may be burnt or a spray of a strong solution of carbolic acid be used, and for the be placed in the vessel that receives the sputa carry out these measures in practice, consumption would have to be placed upon the list of contagious diseases returnable to the board of health, and the present force of existing boards of health would How many social have to be largely augmented The beneficial re-I have not the slightest doubt. Better opportuni-Legislation might in a measure protect the weak ties, too, would be afforded to study the disease, as statistics be gathered

Health boards should, moreover, help to dissem ance is the parent of vice, it is certainly the grand-It is a matter of daily occurrence parent of disease that people who have consumption, and who are constantly expectorating infectious matter, fill posi There are consumptive tailors and dressmakers, consumptive cooks and waiters, consumptive candy; pect for a moment that they are spreading the dis in prevalency by the various modes of life that they have consumption, or at least they persuade themselves that they have not got it They expectorate on the public highways, in church, at or cold or altitude exert much influence ought to be trught how to disinfect them knowledge should come from the government indoors in an authoritative an effective way place, no consumptive should be employed in any capacity in which he may contaminate the clothing, food, or drink of others To obviate hardships in such cases, the government should make provision out of the public treasury for the maintenance of such people as we have to give up their means of lively hood for the public good Whether this be done by pension or by offering an asylum must remain for political economists to decide No hesitancy is felt. in spending millions for the resentment of an insult to our national honor, or for some commercial ad Why should not something be expended in the protection of our people against the ravages of a disease which, in the United States, carries off nearly a hundred thousand people annually? Small remedies will avail nothing with so great an evil Our government should act, and act with gigantic strides

As regards individual effort to prevent the spread of consumption, it must necessarily be confined almost entirely to those who, by predisposition, are likely to develop it They should not only lead strictly hygienic lives in every particular, but should avoid everything that might even remotely lead to the disease, and avail themselves of every weapon The nearer they follow Nature in its dictates as to how to live, the better They must not revel in excess, turn night into day, overload their times ends in phthisis stomachs, overtax their brains, strain their physical generally, as their more favored brothers and sisters its victims do with impunity condition may not fall below par weapons to be used against the disease, it may be well to pass some of them in review

Chmate has always been looked upon as an im-Its importance, however, seems to me to have been much evaggerated soil is undoubtedly a contributing agent to the pro-

 v_{1cissi} ease, and take no precaution against doing so. They tudes of climate have really little to do with the disare often poor people who have to work for their case. Those people who are most exposed to the living, and who, as long as life remains in them, weather seldom die of consumption, whilst those have to earn its support. They do not even know whose lives keep them indoors are its most frequent victims Women, for example, die much more fre quently of the disease than men Nor does warmth the theatre, at their places of business or work—in ored people, who live largely in the warmer portions short anywhere and everywhere that is convenient, of the United States, have a higher mortality rate and the sputa dry up and are carried into the lungs from consumption than the white people, the ma-of others, or find their way into food and drink jority of whom live in the colder portions. In short, First of all, people ought to be made thoroughly consumption prevails everywhere, no matter what familiar with the infectiousness of the sputa, and the climate, where people are compelled, by the de-This mands of society, to crowd together and live much The practical lesson to be drawn from through the boards of health Physicians and public these facts is, that persons who are predisposed to teachers can do much toward creating a proper consumption by reason of the lives of their foresentiment, but they cannot convey the instructions fathers, or the peculiar circumstances surrounding In the next their childhood, ought to adopt a calling in life which keeps them out of doors and away from cities

There is a popular belief that alcoholic drinks are powerful preventatives of consumption all popular beliefs and superstitions, has undoubtedly some truth for its foundation But, as is usual with the bastard progeny of desire, this grain of truth has grown into such immense proportions as to have become the stumbling block of many No one that has carefully studied consumption can have a doubt that their exists some relation betweeen its production and the non assimilation of hydrocarbons Very many cases of phthisis have traces of sugar in the urine, and probably all of them have indigestion of heat producing food These symptoms frequently exist for months before cough and discernible local congestion sets in As beverages containing a small amount of alcohol present a most readily assimilating form of hydrocarbons, they no doubt, when properly used, buoy up the weakened system in its struggle against the bacillus tuberculosis, and often enable it to gain the mastery But what is good in modera tion is always hurtful in excess, and in this instance precipitates the very evil it might otherwise prevent Excess of alcohol and the adulterating ingredients in alcoholic beverages derange the stomach, and thus by interfering with nutrition predispose to consump-In this way a long life of hard drinking sometion

A very noticeable fact in the mortality statistics of endurance, and play havoc with their constitutions consumption is the predominance of females among This is in a measure due to the indoor They must lead correct, orderly life of women, but not altogether The many accilives, and be ever on the alert that their physical dents and diseases incidental to the physiological life As regards the of women greatly predispose to consumption are, however, nearly all of an avoidable character, and have their fountain head in carelessness during portant factor in the production and prevention of Women should be taught from childhood that these the menstrual period and during the puerpenum are sacred epochs, and that during them nature de-A non porous mands rest and especial care The Semitic six weeks' restafter childbirth is true to nature, and should duction of consumption, but not more so than of be observed by every woman who becomes a mother many other diseases Consumption occurs in every Lactation frequently predisposes to consumption, country and every climate on earth, being modified but usually in those cases which have made bad re-

coveries after confinement, and are in want of the likewise no provision, except in first class modern proper food and care which are necessary for a nurs-

Pulmonary gymnastics are powerful weapons against phthisis, and should be especially used by better remain at home, unless his home is in a large those who are unable to extricate themselves from the unhygienic surroundings and circumstances in which their necessities have placed them the use of a gymnasium is very desirable for practising these, it is not necessary volved is ventilating the unused air cells, and any combination of forced respiratory movements that than he would with small means in the most model will thoroughly inflate the lungs will accomplish this Gradually filling the lungs with air whilst retracting the shoulders and extending the chest or taking a deep inspiration whilst extending the arms above the head and expiring whilst placing them parallel with the body, are two simple exercises which do all hence the extremities ought never to be let get cold that is necessary and can be taken without interfering with the most busy life or causing fatigue habit should be made of thus ventilating the unused portions of the lungs, and it should be done at times when the purest air can be secured The most practical germicide that we as yet know of for the bacillus tuberculosis is fresh air, or, more correctly speaking, it furnishes the least favorable habitat for its development A better oxygenation of the blood is, moreover, secured by such exercises, the circulation is stimulated, and, indirectly, the digestion and disease assimilation improved

As regards the hygiene of phthisis, when the disease is once established, it is based upon the same disease they are, however, impracticable, and should principles as that for its prevention Sufficient nourishing food, and sufficient fresh air, these are the sine qua non The prime object in every case of phthisis should be to secure a good digestion and Everything that is done should be done with this object in view Good, nourishing and easily digested food should be taken in abundance, and every care taken that the stomach be not deranged by indiscretions in eating and drinking, or by overloading As soon as the body begins to nourish, the lung trouble will improve As an aid to digestion outdoor exercise is very important Without it the system cannot be made to use up a large Inasmuch as warm climates offer quantity of food greater inducements to keep invalids out of doors, and make bed-room ventilation a little more agreeable, they are highly commendable to consumptives, but they are by no means essential to their well-be- less chance for development A cold climate will do just as well if the patient has the courage to endure the discomforts en- to the progress of phthisis must be built, but it must tailed by it It is much better that a consumptive be a high order of civilization, a civilization in which have home comforts in the worst climate in the world, than that he be compelled to undergo the tortures of boarding-house or fourth-class hotel life live-which banishes want from the earth, gives In all warm climates the houses at a health resort are built for warm weather use, and no provision is made for the stray blizzard that occasionally comes ble from day to day, there is always a marked varia- ucation, and banish all vice and excess from the tion between day and night In consequence of world So long as the "summum bonum" of man's exthe rapid radiation of heat the houses become cool istence is to live at ease, gratifying every desire, and and damp during the night, against which there is tower head and shoulders above everybody else

hotels In many places suitable food is difficult to obtain even at the most extravagant prices all, the average person who has consumption had city, and then he should go into the neighboring country, where he can secure home comforts and Though plenty of suitable food Let him dress warm, take outdoor exercise whenever he can, eat plenty of The principle in- light, nourishing food, take ample rest and sleep, and he will get along much better in his native heath consumption climate

> It is important that the entire body be warmly clad in cold weather Either silk or woolen clothing ought to be worn next to the skin The circulation should be kept equable throughout the entire body, When the feet get cold the lungs become congested Rubbing the body with a coarse towel has a good effect in equalizing the circulation. The ancients recognized this fact, and laid stress on it "Balneum alienum est," says Celsus Sponge baths, if care fully taken, will do good They should, however, be taken in a warm room, and followed by a rest

> Sea voyages used to be highly recommended in the early days of medicine, and theoretically, at least, ought to be beneficial in the first stages of the The ocean offers a pure atmosphere, and frequently the salt air stimulates appetite and im proves digestion In the advanced stages of the never be attempted

> Gypsy life, or traveling through the country by easy stages and camping out, is most beneficial to consumptives, even in advanced stages cients had their patients carried from place to place In the territories most remarkable cures in chairs are brought about by this mode of living Persons unable to walk are hauled in wagons on improvised beds, and it is astonishing what a revivifying effect

constant exposure in the open air has

But, as said in the beginning of this paper, when consumption is once established it is rarely cured, and though much can be done to ameliorate the condition of the consumptive, the most important duty of the medical profession, at the present day, is to lend its aid in bringing about such a change in public and private hygiene as to give the disease

Civilization is the keystone on which the barrier charity for our fellow man is the guiding star-which teaches not only how to live, but how to let others everybody sufficient breathing space, and removes the foot of monopoly from the neck of the working man and the goad from his side, which will remove Though the temperature may be very equa- morbid ideas about dress, society, customs, and edmust be without the necessaries of life in order that the other half may revel in excess, so long as crowd ed tenement houses must tower in the sky in order to let palaces spread out on the surface, so long as soulless corporations can drive man to do more than a whole day's work for half a day's pay, and under simplex) circumstances and surroundings which are in conflict with every rule of health, so long as the rich lead and the poor follow in health ruining fashions and customs, so long as children have their minds made morbid and their bodies ill developed by school cramming processes, so long, indeed, will consump tion continue to be epidemic, no matter what pro gress scientific medicine may make

MEDICAL PROGRESS

THE CARLSBAD "CURE "-DOCENS DR JAWORSKI, of Cracow, gives in the Przeglad Lekarski, under the above title, some interesting details respecting the influence of the springs of Carlsbad on diseases of the stomach The author first emphasizes the fact that the majority of gastric disorders are due to an increased activity of digestion, and not, as had long been thought, to impairment of the secreting power of the gastric mucous membrane of the stomach, or to complete destruction of the digestive action refers to the publications of Reichmann in 1882, in which increased secretion of the gastric juice was said to be the cause of the disease, and also refers to researches on the disease of the stomach by Jaworski. Gluzinski, and others, which illustrated this statement Further investigations had shown by several facts that, in ulcerations of the stomach, hydrochloric acid was increased, and that hæmatemesis, as a result of ulcus ventriculi, was observed when the secretion of hydrochloric acid had risen to the highest point. The greatly lessened the danger of gastric ulcer springs of Carlsbad had been said to stimulate the secretion of the stomach, and to quicken the diges the water and the dried salts of Carlsbad increased the secretion of the gastric mucous membrane when ach given in small doses, when used in large doses, or when taken for a long time, they lessened the secre tion both of acids and pepsine, so that, after prolonged use of these remedies, the secretion was com pletely arrested without any great disturbances in the mechanism of the stomach Out of 232 cases which Dr Jaworski had examined, in 156 he found the cause of the gastric disorder to be increased secre tion of hydrochloric acid The good effect of the springs of Carlsbad in almost all diseases of the stomach was thus explained With reference to the indications for the use of the waters, Dr Jaworski, as the result of numerous internal examinations of forms of gastric diseases The use of the springs of glandular apparatus, by which the power of secreting Carlsbad is indicated i In increased secretion of hydrochloric acid was diminished, and thus a per-

importance, so long is one half of the human race the gastric acids during the time of digestion only (h) per secretia digestiva transitoria) In such cases the use of the Carlsbad waters lessens the sensibility of the mucous membrane of the stomach increased secretion of the gastric acids when the stomach is empty (hypersecretia hyperacida continua When the Carlsbad waters are used in such cases in small quantities, not only the normal but the functional and structural conditions were re-3 (a) In the third stage, which had established been called by Jaworski catairhus acidus v gastrothan hyperacida continua, where the secretion of hydrechloric acid had attained the highest degree, so that the acidity of the non digesting stomach was scarcely less than it is at the period of active diges-In these cases, disturbances of the chemismus of digestion and anatomical changes of the glandular apparatus, and even in the muscular layer of the stomach, were already present. The use of the Carlsbad water in large doses and for a long time, will diminish the acid secretion to a high degree, and produce a considerable improvement in the disease, (b) As, according to all the experimental results which had been hitherto obtained, the round ulcer of the stomach (ulcus ventr iculi rotundum) was attended with the acid catarrh just mentioned, and was probably produced by it, the favorable effect of Carlsbad water in cases of gastric ulcer was satisfactorily ac-counted for 4 Besides the continual increase of the acid secretion, there was still another abnormal He and periodic hypersecretion of hydrochloric acid of nervous origin The difference between these forms consisted in this, that in the former the increased acidity was met with at each internal examination, whereas in the nervous form the increased acidity was only occasionally observed In this latter the Carlsbad water might be advantageously employed 5 In certain neuroses, sensory (hyper asthesia, cardialgia) as well as motory (vomitus nervosus), Carlsbad water is not less useful Dr Jaworski does not remember any single case in which the water had diminution of the secreting power of the stomach been vomited, and this was also true of cases in The which no other liquids, and even no medicament. could be retained in the stomach. In such cases the good result was to be ascribed to the mild effect of tion Dr Jaworski, however, observed that, although the warm and diluted alkaline solution and the free carbonic acid on the mucous membrane of the stom-The use of the waters of Carlsbad is contraindicated in 1 The fourth stage of the secretory debility (insufficientia secretionis acidæ), when the acid secretion was insufficient even during digestion 2 The last stage, which had been called catarrhus mucosus, when hydrochloric acid and sometimes even pepsine was quite absent even during digestion Even in these cases it was worth trying whether the glandular apparatus could not be irritated to secretion by small quantities of Carlsbad water Jaworski further points out that the effect of Carlsbad water was not only a symptomatic one, as believed by many, that it not only neutralized the hyper acidity of the gastric contents, but that it also produced the stomach, distinguished the following stages and permanent anatomical and functional changes in the

manent benefit obtained Whether Carlsbad cure was indicated in a given case should be learned from the internal examination of the stomach. During the time the water was used the progress of the case must be determined from time to time by internal examina It had been proved by several experiments that a too protracted use of the Carlsbad water and salt finally led to complete loss of power of secreting hydrochloric acid On the other hand, it was a known fact that there was no strict causal connection between the subjective disturbances and the object tive changes in the stomach, so that no sure conclusion could be drawn from the former as to the condi- shape, size and color) were soon mastered tion of the stomach It was therefore absolutely necessary to examine the contents of the stomach (11/2 year) at which vision was lost, the very pro chemically from time to time in order to obtain a longed period (upwards of sixty years) of blindness, true idea as to its secreting power, so that it might and the extremely gratifying results of the operation, not be completely destroyed. It should also be borne and it has an important bearing upon some interest in mind that atrophy of the glandular apparatus predisposed to the development of neoplasms in the stomach Korczynski and Jaworski had shown (Klinische Befunde bei Uleus Carcinoma und Magenblutungen, Berlin, 1887) by statistics that malignant neoplasms of the stomach coincided with the above mentioned condition of mucous catarrh, and that the meeting of the New York Surgical Society, on there was probably a more or less close causal rela tion between them -British Medical Journal, January 14, 1888

BLIND SILTY YEARS, IRIDECTOMY, RESTORED TO SIGHT, GOOD COLOR PERCEPTION -DR DAVID MC-

Keown reports the following case

in August, 1883, been blind upwards of sixty years When 1½ year old he lost the sight of both eyes from an attack of small pox perception of light, but the projection of the left was rather to the outer side of the anterior superior spin-There was a dense central opacity extending into the upper half of the left cornea, and the iris was adherent all round to the margin of the opacity performed an iridectomy opposite the transparent cornea above, the only place available for such a I showed the patient in the Ophthalmologpurpose ical Section at the meeting of the British Medical Association held in Belfast in 1884, t e, about a year The condition then was The cor nea opposite the artificial pupil was a little milky, the use of the eye was attended with some difficulty -the pupil being above, and the eye before opera tion having had a somewhat upward position, a considerable effort on the part of the inferior rectus was required (a tenotomy of the superior rectus, alone or combined with the advancement of the inferior rectus, would doubtless be advantageous) presence or absence of the lens could not be determined, the result of a trial with glasses was practically nil, the vision which he had gained by the operation enabled him, when in the streets, to dis pense with the stick which, before the operation, was a necessity, he could count objects of 11/2 line in diameter when about a line distant from each other, he recognized comparatively small differences in size His color-perception was remarkably good, he dis- and an old cavity in each lung -New York Medical tinguished not only the well defined colors, but also Journal, January 21, 1888

different shades of the same color, sometimes even when these differences were not very marked color education was very rapid. When I first spoke to him on the subject I found that he was pretty familiar with green, blue and red Some patients in hospital had given him instruction He came to know green by examining a quilt of that color which was upon his bed, blue by inspecting a blue and white striped shirt which he wore, and red from seeing a lining of that color in a hat He afterwards came to know yellow, brown, etc., from having these col ors shown to him a few times The coins (involving

This case is probably unique, seeing the early age ing questions regarding the conditions under which the functions of the retina may be lost or preserved, and the recognition of form, estimation of distance,

etc -The Lancet, January 7, 1888

EVERTED DORSAL DISLOCATION OF THE HIP—At Dec 28, DR Lewis Stimson reported a case of this rare injury, which occurred in a woman aged 55, who was knocked down by a horse car The (right) injured lower extremity was parallel with the other and with the long axis of the trunk, and was so far everted that the foot rested on its outer border as the patient The limb could be adducted and flexed, lay in bed Edward C, set 63, a fiddler, had, when I saw him but could not be abducted or rotated inward There was shortening of an inch and three quarters trochanter was prominent, and was elevated, the The right eye had not head of the femur could be distinctly felt below and ous process of the ilium By flexing and abducting the limb, and then rotating it inward, the dislocation was easily transformed into the common dorsal variety On increasing the flexion to right angle, abducting and rotating outward while lifting, the original form was reproduced After two or three such failures reduction was made with a distinct sound by maintaining the inward rotation, and after flexion to a right angle, and slight abduction, lifting the limb steadily and with considerable force ing the night following reduction the dislocation re curred, it was again reduced, and the limb was kept in a position of abduction by traction with a fivepound weight It again recurred, was reduced, and recurred, finally the bone was kept in place by traction with a fifteen pound weight, a broad bandage being drawn tightly around both hips No crepitus was felt during the many manipulations, and each reduction was accompanied by a distinctly audible snap The facility with which recurrence took place suggested in the absence of fracture of the acetabu lum, that a portion of the capsule remained interposed between the articular surfaces The patient had in addition to the dislocation, a fracture of the humerus and of two ribs, a laceration of the perinæum,

ANTISEPTIC LOZENCES IN LUNG DISFASES —DR DURANT describes the effect of Dr Albin Meunier's tuberculosis and other affections of the respiratory it of these affections suggested that they might be completely cured if an efficient agent could be found to destroy the microbe, or render the organism impervi ous to its attacks. The antiseptic treatment of affections of the respiratory organs was a method in ac impossible for the following reason. It would only prove effectual if the antiseptic remedies were admin istered in large quantities, these in strong doses ex ercised an injurious and even dangerous action upon the cells of the organism Dr Albin Meunier has which destroy the pathogenic microbe of pulmonary phthisis and other broncho pulmonary affections may be administered in active doses without any danger whatever to the organism Dr Meunier's antiseptic lozenges are composed of carbolic acid, eucalyptol, 10doform, creasote, menthol, etc., 1 to 3 lozenges are given at each meal The beneficial effects of volatile essences in the treatment of broncho pulmonary affec tions have been demonstrated by numerous observa They arrest the evolution of the bacillus, modify the character of the secretions, and diminish the fits of coughing Dr Meunier's lozenges are rapidly absorbed, and the organism is quickly and thoroughly impregnated with the antiseptic sub stances Their odor is observed in the breath, in the urine and perspiration of the patient shortly after the lozenges have been swallowed Owing to the purity of the substances employed, this treatment never disturbs the digestion. The action is prompt and effectual, tonics and strengthening medicines may be combined with this treatment. Under it the padisappear, and the local symptoms are modified -L'Union Medicale, December 11, 1887

GUAIACOL AS A SUBSTITUTE FOR CREASOTE IN PHTHISIS -DR H SAHLI, of Berne, writing on the treatment of phthisis by creasote, remarks that 13th creasote, by which is meant that prepared from the tar obtained by the destructive distillation of beech wood, is a complex substance, the constittherapeutical purposes some simple substance of December 24, 1887 known composition He finds that in the beech creasote, as prescribed in the Swiss Pharmacopæia, prescribed it in cases of phthisis, and found that it reappeared after menstruation

and general condition Some who were confined to bed and suffering from a considerable degree of pyantiseptic lozenges in the treatment of pulmonary revia were unable to retain the medicine, and vomited In some cases, too, it brought on diarrhœa The discovery of the pathogenic microbe the whole, however, Dr Sahli was well satisfied with the guniacol as a substitute for creasote It is a colorless highly refracting liquid, soluble in alcohol, ether, and fat oils, but only slightly so in water The alcoholic solution gives with perchloride of iron an emerald green coloration. The taste and odor of cordance with the most recent scientific theories, its guaracol are more agreeable than those of creasote practical application was, however, rendered almost As solutions of guaiacol deposit resinous substances when exposed to light, they should be kept in colored glass bottles One or two parts of guaiacol may be dissolved in 180 parts of water and 20 of spirit. One or two teaspoonfuls of this may be ordered in a glass of water two or three times a day after meals, or the discovered a means by which antiseptic remedies guaracol may be dissolved in cod-liver oil, which almost completely disguises its smell In this way larger doses can be taken than when the solution in water is prescribed The price of guaracol does not seem to be very much higher than that of creasote -Lancet, Dec 24, 1887

TREPHINING IN MENINGEAL HÆMORRHAGE —A female patient, aged 26, was admitted under the care of MR CROFT, in St Thomas' Hospital, about midnight on Dec 11, in a semi comatose condition She was supposed to have been knocked down and kicked by a horse There was a scalp wound, not leading down to the bone, behind and below the left parietal eminence There was no evidence of fracture During the night she passed into a state of absolute coma, and in the morning had complete paralysis of the right arm and leg, but not of the face Mr Croft trephined in the situation of the wound, removing about two ounces and a half of somewhat granular clot, which was spread out for some distance between the dura mater and the bone The hæmorrhage was tients increase in weight, diarrhœa and night sweats from some vessels into the dura mater (probably posterior branches of the middle meningeal), and could only be arrested by means of pressure About six hours later the power of movement returned in the right side, and her condition gradually improved She spoke for the first time after the injury on the Although not yet recovered, she is still restless at times, and impatient of control, there is no paralysis, the wound is quite aseptic and healing, and the improvement continous A severe contusion of uents of which vary considerably in different sam- the groin was, however, followed by sloughing and ples, and that it is surely desirable to use for cellulitis, for which incisions were required - Lancet,

Antipyrin as a Uterine Sedative - M H the largest constituent is guaiacol, the methyl ether | Chouppe has already called attention to the good of pyro catechin, OH C₆H₄ OCH₃, which constitutes from 60 to 90 per cent of the whole, the rest being chiefly made up of creasol, the mono methyl ether of homo pyro catechin, OH C₆H₃[CH₃] OCH₃ Guaia- a large myoma situated in the posterior wall of the collaboration of creasons. Described to constituent of creasons Described to the state of the collaboration of the constituent of creasons. col being the chief constituent of creasote, Dr Sahli uterus, accompanied by copious hæmorrhage, which had an excellent effect in moderating the cough, hemorrhage, but caused such severe uterine pains making expectoration easier, frequently diminishing that it had to be discontinued the secretion, and improving the patients's appetite phine were administered, these caused the pains to disappear, but at the same time the uterine contractionate of soda (Meditzinskoie Obozrenie, No 5, 1887, tion was relaxed and hamorrhage reappeared Ergot p 508) in ten cases of uramia, in seven of which The at was again administered with similar results tacks of uterine pain lasted two or three hours Chouppe then had recourse to antipyrin An injection, containing 30 grains of antipyrin, was adminis At the end of twenty minutes the pains disappeared M Chouppe then tried the following experiment An injection of antipyrin was given half an hour before the dose of ergot The patient experienced no pain, although there was active uterine contraction, hamorrhage was arrested M Chouppe concludes that antipyrin relieves the pain caused by uterine contraction which is produced by ergot without diminishing the contraction He believes that it acts upon the spinal cord, and might be administered with advantage during parturition to women of irri table temperament —British Medical Journal, December 17, 1887

Extirpation of the Scapula, Reproduction of Bone —A Ceci reports this case The patient had a soft chancre and inflammatory phimosis and recent gonorrheal stricture Five days after circumcision he was attacked with acute osteomyelitis of the left scapula, on account of which the bone was entirely extirpated about a month after the beginning of the disease An Lincision was made, the angle being on the collum scapulæ, the short limb along the spine The operation was then made subperios-Recovery was rapid teal

This makes a total of 47 total extirpations of the scapula, and of 45 cases in which the results are known 9 or 20 per cent have died Ceci and other authors draw the following conclusions The results of the operation depend upon its being performed subperiosteally, upon the age and strength of the patient, and upon the manner in which the after treatment is carried out. It is very necessary to make an angular incision along the spinous process and the inner border of the scapula, the loosening up of the periosteum should begin on the dorsal surface, and then the acromion process, the coracoid and glenoid should be freed The portions of the deltoid muscle must be united by suture The arm must be kept in position by a special bandage Passive motion and faradisation should be begun early and during ossification

Ten months before his last operation Ceci performed total extirpation of the scapula on a young scrofulous girl, 12 years of age, for caries of the subscapula fossa and coracoid process, but he was unable to control the fungous granulations in several fistu The incision was made atypical on aclous tracts count of the fistulæ, but the profuse granulations hindered regeneration The patient finally died of multiple caries and amyloid liver — Centralbl f Chirui gie, No 51, 1887

BENZOATE OF SODA IN URÆMIA -Starting from Cohnheim's theory of uræmia and from the fact that benzoate of soda inhibits the formation of urea within the system, Dr A S Partzevsky, of the Basmannaia In a few cases in which the drug was vomited a hypo-Infirmary for Laborers, in Moscow, administered ben- dermatic injection of grm 1 was efficacious

the patients were suffering from parenchymatous, and in three from interstitial nephritis The drug was given every hour, in daily doses varying between i and 2 drachms It was given either in a solution or in wafers, in capsules, and, where the internal administration was impossible, in enemata. Nine patients recovered, one died Analysis of the cases has led Dr Partzevsky to the conclusion that benzoate of soda cuts short uræmic attacks, the convulsive phenomena gradually disappearing and giving place to deep sleep The latter in "a majority of cases, terminates by passing into full consciousness" Given on the the first appearance of symptoms (headache, sickness, dilation of pupils), the salt may prevent any further development of the fit Albuminuria mostly disappears altogether

STRYCHNING IN AICOHOLISM—The good results obtained from strychnine in dipsomania by N M Popoff, V A Manassem, Partzevsky, Tolvinsky, and Zavadeky have induced Dr S Jaroshevsky (Meditzinskou Obozienu, No 4, 1887, p 332) to undertake an experimental inquiry into the antagonism between the alkaloid and alcohol From experiments made on dogs Dr Jaroshevsky feels justified in drawing the following conclusions 1 Strychnine undoubtedly neutralizes the intoxicating and narcotic effects of alcohol 2 It enables large quantities of alcohol to be taken for a considerable stretch of time without causing the usual organic lesions which follow the use of alcohol alone 3 There are, however, himits beyond which the alkaloid itself becomes injurious 4 Therapeutically, strychnine to the organism should be used in all forms of alcoholism 5 It may be regarded as a powerful prophylactic against alcoholism

ACETO TARTRATE OF ALUMINUM, THE NEW ANTI-SEPTIC -This substance that ATHENSTALDT recommends as an antiseptic, is prepared by mixing a 5 100 solution of acetate of ammonium and a 2 100 solu tion of tartaric acid, the double salt formed being obtained by evaporation Aceto tartrate of aluminum is a brilliant colorless substance resembling gum It dissolves readily in water, has the odor of acetic acid, and has an acid, slightly astringent, but not disagreeable taste. It is soluble in equal parts of water, and the solution remains clear when heated, but It becomes less soluble is precipitated by alcohol when exposed to the air on account of the loss of the acetic acid radicle of the double salt Athenstaldt recommends it as a harmless antiseptic -Journal de Medecine, Dec 18, 1887

Antipyrin in Sea sickness —In the Gazette Hebdomadaire of Dec 2, 1887, Duruy reports that he has administered antipyrin on the voyage between Havre to Buenos Ayres The dose generally found useful was grm 1 5, and 1ts effect was manifested in about ten minutes It was never necessary to give more than grm 3 to give relief in about an hour

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, No 65 RANDOLPH STREET

CHICAGO ILLINOIS

SATURDAY, FEBRUARY 4, 1888

THE NECESSITY OF NATIONAL CONTROL OF MARITIME QUARANTINE

In October, 1887, the College of Physicians of Philadelphia appointed a special committee consisting of Drs J C Wilson, E O Shakespeare, and R A Cleeman, to examine and report upon the condition and defects of the existing principal quarantine stations on our extended seaboard A few weeks later the committee made an interesting and important report, which was published widely through the press, including many medical journals The Col lege of Physicians accepted the report and continued the committee, with instructions to issue an address asking the cooperation of all the medical societies and organizations in an earnest effort to induce the present Congress to adopt such a law as will place the whole subject of maritime quarantine and sanitary interests under the control of the General Govern We have just received a copy of the address issued by this committee, making twenty two printed The fundamental propositions presented in the address may be briefly stated in nearly the words of the committee as follows "a The present meth ods of independent quarantine provided and regu lated by seaboard States or cities, are essentially defective and insufficient for the exclusion from the United States of the diseases against which quaran tine is directed δ It is impossible adequately to protect the public health of the country against the importation of epidemic diseases by independent local maritime quarantine establishments National organization would secure advantages not

ments, however complete," and is therefore necessary for the public safety "d The organization of a National maritime quarantine system in the United States should require 1 That the whole matter be placed under an appropriate department of the General Government, with a central bureau of con trol established at Washington 2 A sufficient corps of medical officers and assistants, with nurses, sani tary police, laundrymen, engineers, and officers and crews for boarding tugs, organized at every 3 The erection of necessary hospital and other buildings, wharves, disinfecting apparatus, wash houses, latrines, etc, in suitable localities, when possible on islands at or near the entrances to harbors and at some distance from the main channel 4 These stations should be organized and fully equipped at every port of entry of the coast, in such a way as to meet the requirements of each portan the measure of its commerce and immigration, and the special diseases to which it is most exposed 5 The cost of the establishment and maintenance of the National Maritime Quarantine should be provided for by appropriations from the National treasury, and not from fees exacted from vessels"

These several propositions are illustrated and sustained by appropriate facts and arguments, in detail, by the Committee The plain direct propositions, however, are sufficient to give our readers a correct understanding of the movement that has been inaugurated by the College of Physicians, of Philadelphia, through its special committee, and for the support of which their active cooperation is solicited The subject is one of very great importance, and should receive the early and most deliberate attention of the profession without delay

REMOVAL OF THE UTERINE APPENDAGES

On Dec 28, Dr Howard A Kelly read a paper before the Philadelphia Co Medical Society entitled "Removal of the Uterine Appendages for Disease in which Pain is a prominent Symptom"-possibly the last gynecological paper of the year, and certainly one of the best It is not a paper of references and quotations, but one written from personal experience, the opinion of the writer in regard to the class of cases suitable for operation, the results to be expected from operation, and in regard to the operation upon neurotic cases pure and simple, conforming closely to that expressed by Hegar in his well known monograph, but differing widely from attainable by independent local quarantine establish. the opinions of many so called authorities in this

field, and still more widely from many views, current in the profession, as to the indications for and against operation, and as to the certainty and permanency and value of the results obtained by operation

It is both important and convenient to make the symptom Pain a characteristic factor in the cases under consideration, since the patients usually apply for relief from that symptom chiefly if not alone, and they are willing to and do suffer "all things of many physicians" in order to get relief And while we emphasize this symptom, we exclude the cases in which size is a characteristic, and are confronted by a large group of mixed pelvic diseases less in size, but not less dangerous, causing more suffering, more certainly undermining the health, and not less important than large fibroids, dermoid or ovarian Of the discystoma, except as to cubic volume eases under consideration, common are ovaries en larged by cirrhosis, ovaries with extensive follicular degeneration, hæmorrhagic ovaries, ovaries containing pus sacs, neuralgic ovaries, ovaries involved in a withering of the pelvic peritoneum with the tubes, and tubo ovarian disease with co existing hydro, pyo, or hæmato-salpına, which names signify an ac cident of the disease—they may be absent and the A prominent factor in causing disease still exist this pelvic distress, especially aggravated at the menstrual period, is, thinks the author, large varicose veins in the broad ligaments

It would be better, thinks Dr Kelly, if "pain, per se, were never considered a sufficient indication for operation, or, at the worst only those cases operated upon in which the most prolonged and pains taking care had failed to relieve, and where the intensity of the suffering must always seriously interfere with the capacity of the patient to enjoy life " It would be better for all such cases if they first underwent a prolonged treatment at the hands of A host of cases of neuralgic the neurologists ovaries that have been sacrificed by the gynecologist would have been thus cured, and many cases that have been operated upon and not reheved, would at least have been spared the ordeal of operation, and the too frequent reproach thus be spared the gynecologist, that he recommended the removal of a woman's ovaries, but she declined and a nerve specialist afterward cured her, and, to make the re flection worse, she has since borne a child factors in the diagnosis of such cases Dr Kelly mentions the character of the pain, the facies of the patient and a peculiar sense of boggy fulness to the gynecologists themselves are apt to place all hope vaginal finger Constipation seems to be one factor upon the operation, like a throw of dice, and to for-

in the causation, but while relieving constipation helps the condition, he has not found that it cures any case of long standing Sequelæ of pregnancy may cause it He rejects removal of tubes and ovaries as in any way assisting a cure In one case sent me by one of the most prominent neurologists in the country last spring, the patient is but little improved, although one of the veins tied and cut off was a half centimetre in diameter. As nothing else seems to do more than mitigate this condition, I propose yet to open the abdomen and simply tie the distended tortuous veins at either end aspirating then, if necessary, and if the patient is no better she will at least be no worse off There is another class, usually classed among the neuralgic cases, and defined by Mitchell as cases in which the expectarcy and concentration of the attention on a normal function leads it to simulate disease in the ex-"These cases if operated upon pression of pain rarely reflect credit upon the operator, and should ever be considered more in the province of the neurologist than of the gynecologist I have never operated on a case of this sort, and never expect to " There is also a small group of cases in which general nervous phenomena seem to subside after a time into a local disease

As to the status of the operation, then, the removal of diseased appendages, small in size, but in which pain is a prominent symptom, Dr Keily con-1 It is scientific, because it deals with cludes that 2 It does more than almost any diseased or gans other single surgical procedure in relieving a large number of cases whose sufferings have been almost 3 In properly selected cases the perunbearable centage of recoveries is 95 per cent, and improving, and the percentage of cures equally large less we adopt the yardstick as our measure of disease, the indications for operative interference are often more urgent than in the case of most cystoma com-5 All the steps of the ing under our observation operation, the technique of the procedure, have now been so widely appreciated, that it may be described as a safe operation

Dr Kelly's standard, in regard to operating is Are the organs diseased? Will stated as follows their removal cure the patient entirely, or will it reheve a large part of the suffering and at least make A result absolutely good is life more bearable always to be desired, but a result relatively good is something to be very thankful for, and grasped in Not only the general profession, but many cases

from the beginning of their treatment to the end, in such a manner that the operation is viewed by doctor and patient as simply a step, at times the only one, again the most important step, or occasionally but one in the fight, in the treatment and progress toward cure Cases often require after treatment, and some of his cases have only left entirely well His operation removed after weeks more of work the focus of the disease, without which he could never have made any progress, but the after treat ment dealt with the disease products that may have been accumulating for years

THE DUTY ON MEDICAL SUPPLIES

At the annual meeting of the Georgia Medical Society, held on January 3, 1888, the following reso lution was unanimously adopted

Resolved, That the Corresponding Secretary enter into cor respondence with other State and lo al Medical Societies, with the view to induce them to act in concert with us in an effort to influence Congress to remove the Import Duty from all medical and surgical supplies, instruments, and appliances

Certainly all will agree that "a feeling of humanity suggests that all medical and surgical supplies, instruments, and appliances, including those used in the diagnosis as well as in the treatment of diseases, should be furnished to those needing them at the lowest possible price " Could our Government be persuaded to remove this duty, the public as well as physicians would be the gainers It is a fact that a large proportion of the medical instruments and appliances offered to the medical profession is of poor quality, and it is just as much a fact that good instru ments cost too much For these reasons many physicians are prevented from supplying themselves with even a moiety of the instruments required for general practice It is a well known fact that the majority of English and German made medical instruments and supplies are better than those made in America, and it is just as well known that such sup plies can be bought at a much lower price abroad than in this country We need not stop to inquire into the causes of this further than to say that the chief cause is the import duty on such supplies, by which the makers of such supplies in this country have the physicians and the public at their mercy Nor do we purpose writing on "free trade" or "protection," further than to say that the best protection a country can give its citizens is to take measures to protect their health

get that it is often more rational to handle the cases articles would compel our home makers to lower their prices and improve the quality of their productsthere would then be no market for poor instruments

> The Georgia Medical Association has acted wisely in bringing this matter directly to the individual mem-The only people that can bers of the profession possibly be hurt by the carrying out of the suggestion are the manufacturers, but even if they are injured, it is demanded for the greatest good of the greatest number

> It is to be regretted that, in the circulars sent out by the Georgia Medical Society, no special or even indirect mention is made of foreign books printed in foreign languages, bound volumes of foreign periodicals, and books by foreign authors printed in their own countries, or in the countries of which they are As the case now stands a U S Customhouse officer, knowing nothing of the value of books, appraises imported books by their weight, or by the number of illustrations in them, or by the amount of gilt on them As the matter is now, the physician in this country pays no duty on the current numbers of an unbound periodical, but if he wishes to com plete a file by buying bound volumes of the periodical he must pay duty on them In what way is the American printer or publisher protected or benefited by an import duty on French, German or Russian text books, or books of any other kind? and how much money is it in his pocket when the Government collects duty on a bound volume of Transactions of a British Society? And by what mental process did any set of men ever hit upon the idea that half a dozen numbers of a foreign bimonthly journal, unbound, do not constitute a book, but that the same numbers glued together and covered with a square foot of pasteboard do constitute a book? Wherein is the justice of charging a physician from forty to sixty cents import duty on each dollar book that he buys from abroad, and allowing a brainless fop to import more than half a hundred "London made" trousers free of duty?

There is another way in which this unjust duty affects the profession Some unscrupulous publisher imports one copy of an English book, makes a cheap and mutilated reprint of it, and sells it to the profes sion as the genuine article By doing this he palms off on the American physician a spurious article, and robs the English author of just compensation for his If the American publishers wish for protection, they might have it in the shape of a prohibitory If foreign made medical supplies were placed on duty on foreign printed books by American authors the free list, the quality and prices of those foreign | -the same law that England has had for many years

We speak more particularly of medical books How many publishers of medical books are there in this country? Not a dozen worthy of the name all of these are in favor of an import duty on books, we believe Is it just that for so limited a number every physician in the country, and through them sick people, should be made to suffer in pocket, and for want of books that they cannot afford to buy at the present extortionate prices?

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, December 8, 1887 THE PRESIDENT, T M DRYSDALE, MD, IN THE

DR W GOODELL read a paper on INTRA-LIGAMENTARY CYST

In it he stated that the three abdominal cysts most commonly met with are the true ovarian, the common parovarian and the intra-ligamentary cysts

The ovarian is typically multilocular, has a pedicle, and starts from the stroma of the ovary, where It always grows into the perito the ovary is found neal cavity, and is probably due to a follicular de-here very dangerous and sometimes impossible generation of the ovaries—which explains its multi- Mounting upward from this region, the sac goes in locular feature

The common variety of so called parovarian cyst is typically unilocular, usually unadherent and thin-It does not bear inside papillary growths, but it contains a clear limpid fluid It is wholly extraovarian, the corresponding ovary being found either pendant apart from it or else plastered upon its walls, but yet wholly distinct. The lining mem brane of this cyst being identical with that of the tubes of the parovarium, its origin is referred by pathologists to this feetal relic To account for its hand, he had had them die in a few months after the single chamber, it is supposed to originate from some detached loop of the tubes, or, especially, from a little cyst always found at the outer end of the hori- bility and low descent of the sac, vertical elongation zontal tube of the parovarium

The third variety of cyst is called the intra ligamentary, sessile or encapsulated cyst From its site between the folds of the broad ligament, from its papillary ingrowths and its quasi malignant nature, and also from the difficulties attending its extirpation, it deserves special description and needs a special treatment

There are two kinds of cysts encapsulated by the The one is a unilocular, papillomabroad ligament tous cyst, the other a multilocular papillomatous cyst Both contain clear fluid The former is probably a cystic degeneration of one of the imbedded vertical foiled tubes of the parovarium, which represents the rudimentary sexual remnants of the Wolffian body is usually more encapsulated by the broad ligament than the multilocular variety, but the connective tis- should then be emptied, but it must not be lessened sue is looser and less vascular

The multilocular intra ligamentary cyst has but a few daughter cysts, each cyst distended by a clear limpid fluid and containing exuberant firm papillomatous growths Its proneness to ingraft itself upon migratory organs, and its firm and vascular union to its capsule of broad ligament, make its removal far more difficult than that of the unilocular variety Its origin is questionable, although the presence of papular ingrowths would point to fœtal tubular relics as the source Some attribute it to cystic degeneration of supplemental ovarian tissue often found imbedded in the broad ligament at a distance from the Others attribute it to the tubular relics in the naro ophoron Lastly, Doron attributes it to stray fætal relics in the hilum of the ovary As this theory met every characteristic of this tumor, viz the papillary ingrowth, its multilocular character and its investment by the broad ligament, Dr Goodell was inclined to accept it. The tumor did not develop into the peritoneal cavity but, growing inwards and into the broad ligament, it parted asunder the true peritoneal folds of the latter. As it burrowed upward it stripped off the peritoneal coat of the womb and bladder, fusing itself to these now naked organs by continuity of structure, and not by mere contiguity Hence, in the operation for its removal, the womb was liable to be badly wounded and the bladder torn open Burrowing downward it uncovered and soldered itself to the ureters, the great pelvic vessels and the rectum, making its separation between the two folds of the mesentery, mesocolon and mesocæcum, and prying them ingrafts itself upon In these cases a portion of the cyst these viscera must be left behind, as the union is too integral to be Another characteristic is the proneness of the cyst wall to burst and to infect the whole peritoneal cavity with papillomatous poison Whether this is always malignant is doubtful, for he had seen patients wholly recover whose entire peritoneal cavity was studded with papillary growths On the other operation

The signs of an intra-ligamentary cyst were immoof womb and bladder, embarrassment in micturition and in defecation, pelvic pains, unsymmetrical abdominal development, and resonance on percussion from bowels carried up in front

The operation for the removal of an intra-ligamentary cyst demands great experience on the part of the physician, and taxes all his pluck These are the cases which are liable to die either on the table or a Formerly, when few hours afterwards from shock a cyst was found to be intra-ligamentary, the incision was closed and the case abandoned Now, thanks to Miner, of Buffalo, the surgeon needs rarely to be

Since the bladder is often dragged upward, and It then lies directly under the line of the incision, great care must be taken not to wound it The cyst in size by the introduction of the hand and the breaking up of drughter cysts, because the flow of blood These innocent masses of papillary granulations, in would be too great, and papillomatous material might fact, so closely resemble the malignant that the miescape into the abdominal cavity reason the opening made by the trocar should be se curely closed The collapsed sac is now drawn out moval of this form of abdominal growth dominal incision so as to leave an uninjured cup like cavity this with the least amount of hemorrhage, the inci cable to the after treatment of abdominal section will also be cut and secured either by ligature or by one having virulent characters and the other benign As the surgeon advances he will pressure forceps have to tie or clamp many blood vessels culated attachment which can be ligated en masse ably because they had been removed earlier Often the whole sac is shelled out of its capsular nest, to injure the ureters, rectum, or the large pelvic ves met with, the adherent portion of the sac must be be peeled off

The vast cavity of the empty capsule is treated in one of the following ways, each aiming to exclude it from the peritoneal cavity (a) The edges of the capsular cup are attached to the border of the ab dominal incision and a drainage tube is put in Through the floor of the intra ligamentary wound a catch forceps is thrust through into the vagina There it is made to seize a winged rubber drainage tube, which is drawn up into the capsular cavity edges of the capsule are now trimmed and sewn with gut the one to the other, so as to exclude its cavity from that of the peritoneum

Whenever neither of these modes can be adopted one large drainage tube, or even two of them, should

be introduced into the pelvic cavity

DR DRYSDALE said that the paper of Dr Goodell covers the ground so thoroughly that he could add but little to what had been said One important point is the extreme thinness of the cyst wall often met with in these cases, which, in his experience, had made it almost impossible to get the cyst away with Another difficulty peculiar to this form of tumor was the risk of wounding the great blood vessels of the pelvis when the cyst had burrowed under or become incorporated with them

Dr Drysdale understood Dr Goodell to say that he believed that all operators, in removing these true papillomata always prove fatal some writers in the curability of these growths is the twenty-third day, in charge of Dr Gabel founded upon the error of mistaking a benign growth remains well three years after the operation which resembles them for true malignant papillomata

For the latter croscope alone can distinguish one from the other

DR J PRICE has not had experience in the reof the abdomen and the capsule is divided, little by pleased with the free use Dr Goodell makes of little, in a circle on a level with the edge of the ab drainage tubes, he himself has used three at one The sac wall is then enucleated time in complicated operations. He is wishing for To do some form of perfected continuous irrigation applision should begin at the lateral border of the sac, He has had his greatest experience in the removal of where the spermatic vessels lie After these are se pus tubes, and has met with a mixed ovarian and cured, the incision is extended to the site of the parovarian growth in many of his patients. Mr Tait womb, where will be found the uterine arteries, which had described two varieties of papillomatous cysts,

DR B F BAER has had some experience with this The at class of tumor He has operated on at least four tachment to the womb is left for the last, and it can cases so far as he can recall at this moment, but they then usually be brought outside of the abdomen, had not been quite so severe nor the tumors so large when it may be often converted into a sort of pedun as the typical case described by Dr Goodell, prob-

The first case was one of a double tumor of very without any approach to a pedicle In the deep por rapid growth, sent to him by Dr Gabel, of York, Pa tion of the enucleation great care must be taken not. The patient had been perfectly well so far as she knew eight months previously, but at that time she suffered When firm adhesions to important viscera are from an attack of acute urethritis and vaginitis, followed by a burning pain in both ovarian regions cut off and left behind, but its secreting layer should Soon she found that the abdomen was enlarging, especially on the right side. Seven months after this date, when he first saw the patient, she was much emaciated, and the abdomen was greatly distended by an irregular, fluctuating tumor There was a deep sulcus extending from the lower border of the tumor diagonally upwards The uterus was soft, high up and drawn to the left When the abdomen was opened two large tumors were revealed The left was tapped and removed first, because it was upper-The most It had a short, thick pedicle, which was transfixed, ligated and dropped The larger tumor was next emptied, and it was now found that it had a deep pelvic attachment Further examination showed that the tumor was subperitoneal and closely adherent to the uterus, as well as to all the pelvic viscera Enucleation was begun, and after a laborious effort, during which considerable bleeding occurred, the tumor was separated, leaving a large open wound in the broad ligament This was transfixed and tied en masse as a pedicle, making a very thick stump Just as he was about to close the abdominal wound the ligature slipped off Great hæmorrhage followed this, and it was feared the patient would succumb before it could be checked, but by the rapid application of catch forceps one after another it was controlled until ligatures could be placed The wound in the broad ligament was finally united by placing ten or twelve interrupted silk sutures tumors, had met with the accident of opening the fully cleansing the abdominal cavity of all clots the He was glad to say that in an experience incision was closed—without drainage—and the paof twenty-six years he had never been so unfortunate tient put to bed more dead than alive It was thought Dr Drysdale believed that that she could not react from the shock, but she ral-The faith of hed and made an excellent recovery, going home on

The second case was also a double tumor of rapid

One or both of the cysts had burst and seem to be necessary probably discharged into the bowel on two occasions lent recovery from the operation The after history before he saw the patient She presented an appearance of great pallor and emaciation The abdominal to Dr Baci's operation she consulted Dr Kelly, who surface was rather symmetrical and fluctuation was performed a third laparotomy The uterus was drawn high up and it very marked was not freely mobile. When the cyst was exposed the uterus, and it presented some of the symptoms it presented a deeper color than that common to the of that disease. The womb seemed to be one with ordinary ovarian cystoma. The cyst wall was thin a hard tumor, the size of a child's head, which occu After tapping, it was found to have a deep pelvic pied the right iliac region, and the patient suffered pedicle was ligated smaller tumor existed on the left side peculiar shape, being elongated and deeply seated in or broad ligaments was made Laparotomy conthe pelvis It was entirely subperitoneal. The peritoneum extended out from the uterus, spreading over ligaments and uterus to be one mass the tumor and approaching the abdominal wall as is his former experience, he began by ligating the Falsometimes seen in a fibroid tumor of the uterus which lopian tube and larger blood vessels before beginning has pushed that membrane upwards in its growth The cyst extended along the line of the colon, and rhage at first he was not sure that it was not that organ greatly distended by gas He soon determined that it contained fluid and that its general appearance was similar to that just removed The fluid was evacu-The fluid was evacuated, when the cyst collapsed He hesitated as to the proper course now, because of the broad base then tore a small opening through the posterior surand deep attachment of the tumor and its close adhesion to the sigmoid flexure stitching it to the abdominal incision and draining, but he did not, and was sorry soon after that he had not carried out his first idea, for his attempt at enucleation of the tumor was attended by so much hæmorrhage, although ligatures were applied freely, that he felt compelled to cease his efforts He had separated at least six inches of the descending colon from the cyst wall when he found that the latter dipped down so deeply into the pelvic excavation that he concluded that it would be too hazardous to finish the operation He next tried to strip off the from the operation lining membrane, but could not do so safely because of its intimate relation with the large blood-vessels He finally drew out all that was separated and ligated the entire mase The stump was dropped and a dramage-tube inserted The patient recovered, but she still has an occasional fistulous poisoned by the virulent character of the cyst conopening at the site of the drainage-tube not think that this cyst was papillomatous, but it was ity were not affected at all One explanation of certainly intra ligamentous

In another case he performed secondary ovariotomy for a small tumor of this character in a case of benign at an early stage of its development and may hystero-epilepsy and metrorrhagia face of the tumor looked not unlike the pregnant parovarian intra ligamentary cysts are very thin, as uterus in color and vascularity Its outer wall was mentioned by Dr Drysdale interlaced with a network of veins, some of them as in his paper to the danger of wounding the great veslarge as a quill it to be so deep in the pelvis and so closely attached Dr Drysdale overlooked to the uterus, Fallopian tube and broad ligament that tion as an application to cozing surfaces they seemed to be one mass, the whole attached by used it freely, in full strength, over the whole capsular a broad surface to the pelvic floor almost filled with papillary material and it was diffi cult, on account of adhesions and the deep location of the tumor, to remove it without the escape of some very fortunate not to have wounded the bladder in of this material into the peritoneal cavity Irriga such operations, for all the eminent operators have tion was not used, nor was drainage, as they did not reported cases

The patient made an excelof this case is of value A year or two subsequent

A fourth case had been diagnosticated fibroid of Enucleation was necessary and a thick from severe metrorrhagia. The left side was some It was now found that another what similarly affected, but not to the same extent This had a Under ether diagnosis of cystic tumor of the ovaries firmed the diagnosis and showed the tumors, broad the enucleation, and had no trouble from hæmor-By this means the larger tumor on the right side was safely removed But the one on the left side was so firmly fixed to the womb that to remove it would have required hysterectomy as well Even this could not be done because of the pelvic attachments of the tumor It could not be drawn up face of the broad ligament and shelled out the lining He first thought of membrane of the enclosed sac Free hæmorrhage occurred, but was controlled by sponge packing Free drainage was used, the patient recovered

In still another case operated upon recently he was compelled to remove the right cornu of the womb with the tumor, because of the close connection of the small tumor to that organ and the tube A similar condition existed on the left side. The tumors were papillary, and the patient had suffered from great hæmorrhage at intervals during two years Drainage was used, and the patient has recovered

Dr Baer did not consider these papillary cases malignant in the sense that they will return after operation, they were certainly not epitheliomata

DR GOODELL's experience tallies with that of Dr Kelly, that some of his patients were eventually He does tents, and died a few months later, while the majorthese varying results may be expressed in the statement of Virchow that a papillary growth may be The walls of these The upper sur- afterwards take on malignancy He had called attention Exploration with the fingers showed sels and mentioned a case in his own practice, which He likes Monsel's solu-The cyst was cavity by means of a sponge saturated and squeezed out, or he wets the end of his finger with it and ap plies it to bleeding points Our President has been (To be concluded)

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, January 17, 1888

THE PRESIDENT, I SOLIS COHEN, M D, IN THE

DR LAWRENCE F FIICK read a paper on THE HYGIENE OF PHTHISIS

(See page 138)

DR T J Mays said view which I did not think existed to any extent in ployed in every case of phthisis The author attributes the existence of DR S Solis Cohen said pulmonary phthis's to the bacillus tuberculosis Probably the best evidence of this is found in the with any of the theories advanced report was made a few years ago of nearly four hundred beds nearly all those who were connected with the hos pital as physicians, nurses, etc., during this period hospital as the source of contagion Dr Brehmer gives some remarkable results in his book on the Etiology of Pulmonary Tuberculosis He states that in the town of Gorbersdorf, where his hospital is lo cated, that the mortality rate of the native in habitants from phthisis twenty years ago, at which time the hospital was established, was 50 per cent greater than at present, notwithstanding that during that time there have been present about twelve thousand consumptive patients who have freely mingled with the citizens It also often happens that at health resorts for consumptives the physician himself is the subject of the disease, and yet, under such circumstances, frequently improves in spite of the presence of the tubercle bacıllı

The author advocates a strict quarantine against Precisely such a quarantine was carried out in Naples for sixty years up to forty years ago, but the results were entirely negative

In another statement the author is, I think, not borne out by facts He states that females are more hable to the disease than are males I have recently gone over an enormous amount of statistics, col that females are much less hable to the disease than The report of my statistics will be found in a well developed apical expansion On the whole, these points is very far from being clear

Dr I Daland said I think it has been well as certained that an hereditary predisposition does play an important influence in the causation of phihisis It seems to me that this fact still remains well established With reference to the climatic treatment of phthisis, I do not think that this can be dismissed with the few words which the author has There seems to me to be no doubt that in the early stage of the disease, particularly in young men, that a change to a colder climate is of benefit The disinfection of the sputa is a point on I have listened with much which sufficient importance is not usually placed interest to this remarkable paper, which expresses a is a matter of the greatest moment, and should be em-

I believe that it was I Mr Spencer who thanked a certain philosopher for do not think that such a view is borne out by the benefiting him by expressing opposite opinions in a facts If it were true that phthisis is propagated by forcible an eloquent manner. I can make my accontagion, those who are the most exposed to the knowledgments to the reader of the paper in similar disease should be those who would be most liable to language. I admire the suggestiveness and the vigor The facts prove that this is not the case of his paper, but I find it almost impossible to agree history of Brompton Hospital, of London, when the practice advocated, physicians of experience are all This hospital had of nearly one mind, nor has Dr Flick permitted been in existence thirty six years. It has a capacity himself to be led astray in this matter by his theories The history includes The question of the omnipotence of the bacillus tuberculosis is one that deserves to be ventilated on every occasion I have already to night quoted the Not one case of the disease could be traced to the remarks of Dr B W Richardson in another connection, but as I consider him the master mind in medicine of the nineteenth century I need offer no apology for again quoting him He says, "What have we done, to be visited in the heavens above, in the earth beneath, and in the waters under the earth, with the pestis bacillorum, which is now regnant?" Everything is bacillus Dr Richardson believes that it will not be long before the bacillus of pregnancy will be discovered

I think that Dr Flick has himself given the strongest argument against the bacillophobic views he ad-The chain of events graphically described from several starting points invariably concludingmalnutration and consumption Malnutration is the fundamental, the bacillus is the accidental be that the bacillus does, when inoculated, under certain circumstances, cause tuberculosis, there is some doubtful evidence bearing on this point which cannot be dismissed in a discussion of this kind Even admitting that inoculating with the bacillus will cause consumption there is no evidence that the inhalation of the bacillus will cause the disease The inhalation of sputa and the inhalation of the lected in this country and abroad, and they show bacillus are two different matters The pus cell and the coccus pyogenes are not at all synonymous They may be in the mixture which goes to make up the Medical News of January 7, 1888 The fact the sputum, an element similar to those bodies which that the disease is less frequent among females may we know as the leucomaines and ptomaines, which, The fact the sputum, an element similar to those bodies which be accounted for by the fact that they have a more in a person predisposed and in a low condition, may extended apical motion than the male, and we know be capable of exciting the disease by interference that consumption never occurs in any one who has with nutrition or otherwise. The evidence on all one cannot help but be pleased with the paper, but ing for argument's sake, that the microbe is one of while I admire it, I cannot agree with all the state the existing causes, we must still recognize, as the reader of the paper has pointed out, that the bacillus is everywhere present, and no matter how tim of the disease powerful are the means brought against it, they are deal of thought, and have observed the effect of incapable of destroying it or of dislodging it, when it many remedies and of hygienic conditions. I do is once in the lungs bacillus in the lungs, at the very next breath the got my exact ideas on the subject. I hold that enemy is once more within the strong-hold fore, the only rational thing to do, to prevent con-starting-point on malnutrition. I hold that without sumption whether the bacillus be a cause of the malnutrition and malassimilation such a thing as disease or not, is to build up the nutrition of the individual by the measures mentioned to night and by We must utterly discard the misleading, and therefore destructive, idea that by bringing his digestive apparatus is out of order he will never germicidal agents against the bacillus tuberculosis fall a victim to phthisis, no matter of what his parents we can benefit our patients in the least patient and the bacillus will take care of itself

the tuberculosis diathesis—and that there is such a tients, is not well grounded diathesis universal experience goes to prove-is a very important matter, and, notwithstanding the views advanced, I think that every one of us should warn against the marriage of those whom we have reason to suppose would transmit such a woful in-The question of baths in consumption is There are two methods of failure an important one of function in consumptive patients which we must The one is a failure of assimilation, and the other, no less important, is a failure of excretion The skin is an important excretory organ, and it cannot be kept in the best functional condition without While we may not plunge a patient into a cold bath, we must see that he keeps the skin of the United States entire body clean, and as active as circumstances possible, or if not, daily sponging of the entire body should be insisted upon This will often relieve pathological sweating It is also a question of the however, that a mistake in diagnosis is often made greatest importance in how far we shall check sweating by drugs, whether to reduce the skin to a dry and hot condition, is not far more dangerous than the very moderate perspiration for which atropia reality it was a case of phthisis from the beginning This question and other drugs are frequently given must, of course, be decided in every case upon its own merits, with due attention to all the circum-Still I feel that it is often better to depend upon our general measures for the relief of this and other special symptoms than to resort at once to the attention it deserves symptomatic medication

I would ask Dr Flick with DR M PRICE said reference to his experience with inflammatory conditions as a cause of phthisis I do not believe in heiditary consumption I believe that 90 per cent of the cases of consumption come from some in flammatory condition as the starting point I am a firm and positive believer in the inflammatory origin of consumption In nineteen years of practice I have not seen more than three or four cases in which I could not discover an inflammatory cause heve that without this inflammatory starting-point,

consumption is impossible

I felt considerable hesitation in DR FLICK said presenting this paper, as I knew that the opinions subject I have strong convictions on the subject, clavicle slightly shortened, and find it answers admirhowever, as I have myself been the unfortunate vic- ably Under its loops, over each shoulder, two straps

I have given the matter a great Even if we could destroy every not know that those who have discussed the paper There-consumption is entirely dependent for its initial consumption cannot take place I think that when one is run down he is then a fit subject for the bacillus tuberculosis, and unless he is run down and Treat the or his grandparents died

The objection based upon the fact that nurses in The question of the marriage of those that inherit hospitals do not contract the disease from their pa-The nurses and others connected with a hospital are generally well nourished, as they get everything that is necessary to keep up their condition. When they get below par

they fall victims to the disease

I believe that no consumptive patient derives benefit from climate in itself. The benefit comes from the change of life and from the out-of door life If the patient lives an out-of door life and takes nourishing food he may recover If he goes to any climate and stays in the house he will die

With regard to the relative frequency of the disease in males and females, I would state that my statistics are drawn from the census reports of the

I have no doubt that inflammatory conditions of Baths at a moderate temperature, when the lungs have some bearing on the production of the disease, masmuch as a person who has had pneumonia is left in a depressed condition I believe that a case is often considered to be one of pneumonia when really it is a case of phthisis said that pneumonia has run into phthisis when in

I have brought this subject forward with the hope This is a matter that is too of exciting discussion There is no disease that causes much neglected as many deaths as does consumption, yet we have become so accustomed to it that we do not give it

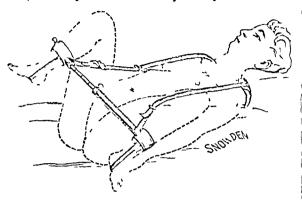

Stated Meeting, December 28, 1887 THE PRESIDENT IN THE CHAIR

DR W W KEEN read a paper on

A MODIFICATION OF THE "PERINEUM DISTENDER" TO AVOID ITS INTERFERENCE WITH RESPIRATION

In the frequent use of the "permeal distender," I have found the strap which passes under the nape of the neck very objectionable This strap flexes the legs, and supports their weight While doing so the weight of the legs pulls the head and neck strongly forward, and thus often seriously embarrasses the respira-To avoid this, I have had the wooden shoulderpiece of the old Day's apparatus for fracture of the

are passed, with a buckle turned wrong side foremost administration of this food should always precede at one end The other free end, after passing through the time of operation by three or four hours this buckle in the armpit, then is buckled to the all, it is necessary that the patient have a chance to cross piece between the legs. By this means the recuperate her strength and prepare for the mental pressure is brought on the shoulders instead of the and physical ordeal of the operation by having a rest neck, and respiration is entirely unimpeded

LI have also had two straps attached at right angles to the straps for the legs By this means the leg straps can be secured above the calf as usual or at In this last position the new straps, by the ankle passing under the foot soles, more completely flex the legs, and get the feet out of the way of the operator DR CHARLES MEIGS WILSON read a paper on

THE TECHNIQUE OF OOPHORECTOMY

Preparation of the Patient —In all cases, it is ad visable for the operator to have the patient under observation some little time before the operation Too much condemnation cannot be given to hasty and ill considered operations The urine should be carefully examined, in order to see that it is free from Neglect of this rule has doubtless oftentimes been the cause of the patient's death gastro intestinal canal should be in a state of healthy function, and the day preceding the operation all portions of the intestine should be thoroughly emp This is best secured by the administration of some gentle laxative, such as the compound liquorice powder, in 1 or 2 drachm doses, or, if there be some torpidity of the liver, by the administration of 12 of a grain of calomel every hour until the bowels are opened, care, however, being taken in both cases not to purge the patient, and not to set up any excessive peristalsis On the morning of the operation, the rectum should be emptied by an enema and, in order to prevent the accumulation of gas in the intestines and to avoid gaseous distension of the intestines, it is generally best to put into the laxative enema a little turpentine emulsified with the white of This, as a rule, relieves the intestines of an egg any accumulation of gas present in them, and at the same time is not irritating The patient should have, on the morning of the operation, a hot bath, which will add to her comfort and remove any sebaceous matter on her abdomen, it is best to have the patient sponged with alcohol after the bath Also, on the morning of the operation, the patient should ab

In bed of at least three days before the operation, and this is especially important if the patient has come on a long journey and is fatigued with travelling

The Surroundings of the Patient —By election, it is always best to operate upon the patient in a hospital, particularly if one have a hospital ward especially devoted to this class of work, in preference to operating upon the patient at her own home The reasons for this are obvious Prior to the operation, it is better that the patient should have a room remote from the operating room with all its appalling armamentarium and paraphernalia, in order that she may not become frightened or worried by seeing the preparations for the operation. It is best on the morning of the operation to bring the patient to a room adjacent to the operating room, where she may rest until the an esthetic is administered room should be bright, cheerful, airy, and spacious, and should have pictures on the walls, or something in the room to divert the patient's attention patient should also be constantly attended by a nurse during the hours preceding the operation, in order that she may not become lonely and allow her mind to dwell upon the operation It is best, both before and after the operation, to exclude rigorously the friends and relatives from access to the patient, and to have the patient give herself up entirely to the operator, in order that he may control her movements without the interference of relatives and friends

The Operation — The room for the operation should, when possible, have walls and floors that can be thoroughly cleaned and disinfected, in order that the operation may be conducted in an aseptic atmosphere For this purpose, the operator's own operating room has tile floors and glazed tile walls, so that the whole place can be flooded out with water, and placed in a thoroughly clean condition operating-table of plain wood, painted, resembling in size and shape the ordinary kitchen table, is all that is really necessary One or two stands of light construction, and upon large castors, in order that they may be readily wheeled from one portion of the room to another, and a chair for the assistant who holds the patient's limbs, are all the furniture re-A large can containing distilled water and an alcohol lamp or gas burner under it so as to maintain the water at a fixed temperature, and a tube running from the can to the table, so that at any time during the operation the whole operative field can be flooded, is also in the room The sponges are used over and over again until the sponge fibre commences to show evidences of disintegration These are always of the finest quality and for the most part those which are known as potter's sponges, or thin, flat sponges For the first time, they are prepared as follows

All of the dust is first beaten out of them are then immersed in a 15 per cent solution of hydrostain from taking any food, unless it be a cup of chloric acid for forty eight hours. They are next strong coffee or a little milk and lime water. The thoroughly washed until all the acid is removed from They are next their interstices hour in a solution of permanganate of potassium, 180 grains to 5 pints of water. This is done in order to the patient, ready to give immediate aid to the bleach them The hydrochloric acid solution is, of operator course, for the purpose of removing any mineral matter that may be in their meshes. They are again abdomen is wiped off with a little ether, in order to washed in running water and placed in a solution remove any greasy matter that may be present upon consisting of 10 ounces of the hyposulphite of sodium, 5 ounces of hydrochloric acid and 68 ounces of bichloride solution (1 1000), and carefully dried, They are allowed to remain in this solution for a period of from two to four hours until thoroughly bleached running water where they are allowed to remain for several hours containing solution of bichloride of mercury (1 1000) fied himself that the patient is sufficiently anæsthetized and hermetically sealed until the time of operation After an operation they are washed out in warm the surgical degree—the abdomen is opened with a water, then soaked in a solution of sodium carbonate few rapid strokes of the knife, without the use of the half ounce to a pint of water for three or four hours, then rewashed in warm water and put back in the I 1000 bichloride solution ready for use again instruments are all nickel plated, with the exception the subperitoneal fat is reached They are prepared by being of the cutting edges first scrubbed with glycerine soap and then immersed the linea alba if possible, so as not to open the sheath for several minutes in boiling hot water then laid upon towels which have previously been alba, no time is lost in dissection in order to reach it, immersed in the solution of the bichloride of mercury (1 1000) and thoroughly dried by superheated rectus muscle The rule with reference to the incision They are then ready for use are kept in a 5 per cent solution of carbolized oil The ligatures and sutures are kept immersed in a They solution of bichloride of mercury (1 500) are always washed in distilled water immediately be fore being used silkworm gut has been found most satisfactory, clamped and held in position by perforated shot | numerous, it is a great deal better to enlarge the in-For ligatures the twisted Chinese silk, imported by Mr Snowden of No 7 South Eleventh St, Philadelphia, has been found to be the best For anæsthesia, chloroform has been used instead of ether, unless the The reason operation is likely to prove a long one that chloroform is preferred to ether is the author's be lief that chloroform when properly and carefully administered is nearly as safe as ether, and because with chloroform, as a rule, there is none of the bron chorrhœa and gastric disturbance which usually follow When ether is given, it the administration of ether is found that a less amount is required and that the anæsthesia is more satisfactorily induced and maintained by administering the ether upon the Allis in-Where haler rather than with the ordinary cone chloroform is employed, it is usually administered by means of the shield devised by Professor Billroth and used in his clinic

The temperature of the operating room should be about 75° It is best to cover all portions of the patient's body with light blankets, with the exception of that portion of the abdomen involved in the seat of operation An assistant sits at the foot of the operating table, and receives and holds the patient's however, to leave sufficient of the pedicle to prevent limbs, passes the catheter just before the operation, and, when necessary, with the finger in the vagina, lifts ovary, tube, or pedicle up into the abdominal the pedicle with the Martin forceps for a few moments wound, as the operator may desire A trusted assist- and then, if there be no evidence of hæmorrhage, it

Then they are placed for half an ant takes charge of the anæsthetic and does nothing else The chief assistant stands on the left side of

Immediately preceding the operation the patient's the abdominal wall, and it is then washed with the especial care being taken to see that all the little folds about the umbilious are perfectly clean They are next thrown into troughs of there be an abundance of suprapubic hair, sufficient is removed to give a chance for extending the incision Afterward they are placed in jars downward if necessary The operator having satis-—and sufficient is meant that she is anæsthetized to director

The operator can readily judge of the depth of the The abdominal wall, and really no care is required until The abdomen is opened in the median line, care being taken to strike They are of the recti muscles If we fail to strike the linea but the abdomen is opened, if need be, through the The needles best to be followed is to make it as small as is compatible with the removal of the ovary or of the growth Where oophorectomy is performed, an incision one and one half or two inches in length is amply suffi-On the contrary, where an ovarian cystoma For suturing the abdominal wall is to be removed, and the tumor is a large one, or perchance, semi solid, or where the adhesions are cision in order that the growth can be readily gotten at, rather than to attempt its removal without knowing exactly what we are doing, and without having room enough to raise it up through the abdominal No care is taken to prevent the blood from the wound in the abdominal wall escaping into the peritoneal cavity, and although it is always best to avoid allowing the contents of a cyst getting into the abdominal cavity, it is thought best to complete the operation rapidly, rather than to avoid the escape of the cyst contents into the abdominal cavity 11, however, we are dealing with a pus tube, then, of course, the greatest care must be used to avoid the escape of the pus into the peritoneal cavity, owing to rupture of the tube wall The pedicle is transfixed rupture of the tube wall with an aneurism needle, the penetrating arm of which is at right angles to the handle, and tied with a stout twisted Chinese silk The loop of the ligature carried through the pedicle is held as the needle is withdrawn, and divided, each half of the pedicle is tied, and then the whole pedicle is tied with the remaining parts of one of the ligatures The pedicle is severed close to the ligature, care being taken, the ligature from slipping An important precaution to take to avoid secondary hæmorrhage, is to hold

is dropped back into the peritoneal cavity there is any tendency to hamorrhage from the pedicle, it is lightly touched with the flit button of the Paqueadhesions, and there is oozing from those which have perchloride of iron of distilled water at a temperature of 100° F It is and rally the patient from the shock sary, because, as has been frequently noted, the pa-bandage of opera flannel fastened with safety pins tient's respiration becomes embarrassed, and oftentimes temporarily ceases during the time that the operation, the patient eats absolutely nothing the cyst with the aspirator

patient is then turned on her side and all the water tion of food allowed to drain out that will The sponging is continued until all tion of animal broths and soft food shreds of coagulated blood are removed, and until when the sponge is brought up only a pale pinkish arise leading us to suppose there is something wrong fluid escapes when the sponge is squeezed

When we are sure that all hæmorrhage has ceased cavity within the peritoneal cavity, the intestines, if any If necessary to lift loops of intestines out of orrhage into the peritoneal cavity wrapped in soft towels kept moist and at a tempera ture of 100° F placed there in order to absorb any blood which by a little tuft of the bichloride wool silkworm gut, is used in the introduction of the glycerine with the point of the needle, and the free ends of has elapsed from the date of the operation tightened It is found that as a rule, this makes a ling a third of a tumblerful as a dose

Where neater approximation of the edges of the wound The sutures are fastened with perforated shot abdomen is carefully washed off with the solution of lin cautery Where the ovary is bound down by bichloride of mercury (1 1000), immediately the wound is closed There is then poured over the been torn asunder, they are lightly touched with the surface of the wound a liberal quantity of Keith's finger, which has been rubbed against a piece of the dressing (12 per cent solution of carbolic acid in The abdominal cavity is then (glycerine) Over this are laid five or six thicknesses invariably flooded for about five minutes with a stream of Lister's gauze, and over the first thickness of the I ister's gauze (the one nearest the wound surface) surprising to see how, when a patient is profoundly is dusted a liberal quantity of pulverized iodoform shocked, this intra peritoneal irrigation with hot water for equal portions of iodoform and boracic acid will immediately restore the equilibrium of the pulse Over the Lister's gauze is then placed a thick wad of In operating, bichloride wool—that is wool that has been wet with care should always be taken not to handle the ovary |a| solution of bichloride of mercury (1 1000) and or the meso salpina any more than is absolutely neces thoroughly dried. Over this dressing is applied a

After Treatment —For the first twelve hours after ovary is in the grasp of the operator's fingers. Where at the end of that time, the patient has rallied from there is a cyst of any size, its contents are aspirated ther shock, and there is no hyperpyrexia or other with Mears' trocar, but where the cyst is small, we symptoms of evil import, we commence to feed the prefer to enlarge the abdominal wound, rather than patient with weak tea, ice cold, giving two or three to delay the operation by evacuating the contents of drachms every hour. This we have found by experience to be the best way of quenching thirst and The Toilet of the Peritoneum -First, as noted furnishing gentle stimulation without overtaxing the above, the peritoneal cavity is thoroughly irrigated stomach or producing nausea or emesis. At the end with distilled water at a temperature of 100° F The of twenty four hours we commence the administra-This is preferably milk if the patient She is then again will take it and the stomach retain it turned upon the back and the peritoneal cavity stomach be irritable, we give Koumiss or Matzoon in carefully sponged, the intestines and mesentery place of milk. Unless the stomach rebel, the use of being held out of the way with one hand while with the milk is continued in half ounce doses with a litthe other the operator carries a sponge attached to the lime water, and after a few hours it is alternated a bayoneted sponge holder, first into the retro vaginal with beef or chicken tea, on the fourth day, if the portion of the peritoneal cavity and then into both patient is doing well, we commence the administra-

The dressing is never changed unless symptoms with the wound, or trouble within the peritoneal The sutures are removed on the seventh or eighth day Drainage is never employed, unless we have been left out of the abdominal cavity, are have reason to fear tissue necrosis as the result of carefully replaced and the mesentery is folded over traumatism of the operation, or unless we fear hæm-If symptoms the abdominal cavity, they should be carefully arise which indicate drainage, it is a very easy thing to open the lower angle of the wound, and insert a Upon the mesentery is placed a drainage tube, where a drainage tube is used, glass thin, flat potter's sponge which extends half an inch is the preferable form Great care must be taken to or more around all portions of the wound This is see that the mouth of the tube is thoroughly closed may escape from the needle punctures Its centre necessary to remove any fluid contained in the is grasped by a hæmostatic forcep in order to facili drainage tube, it is best done with the long uterine tate its removal after the sutures have all been intro-syringe, and after the removal of any fluid it is well A strong, stout needle threaded with a loop to pour along the sides of the drainage tube a few of catgut or Chinese silk, in order to snare the drops of Keith's solution of carbolic acid and As a rule, the patient is kept in the hos-The sutures are all introduced from within pital for a week after the sutures are removed, and is outward in order to avoid wounding the intestines enjoined from travelling any distance until a month each suture are held in the bight of the hemostatic bowels, are moved, as a rule, upon the sixth day, forceps When the sutures are all introduced, the preferably by a gentle saline Recently we have flat sponge is removed and the central suture is first found Rubinat water the best for this purpose, giv-

Great care should be taken by the operator to know exactly how many homostatic forceps, instru ments, and sponges are present in the room prior to the operation over the instruments and have the count verified by an assistant, both before and after the operation, in order that the operator may avoid the distressing accident, which has happened now many times of leaving a hæmostatic forceps of sponge within the abdominal cavity

The operation may be performed at any time, with the exception of the menstrual period, and five

days before and five days after it

Complications arising in the After-Treatment -A majority of the cases that die after oophorectomy perish from sepsis Where proper care is taken in the preparation and management of the operation to have everything about the patient, including the at mosphere of the operating room, the patient's body and clothing, the instruments, the dressings, and, above all, the conduct of the operation in aseptic condition, experience has shown that an extremely small per cent of patients die from this cause Careful attention to the rules described in this paper will do a great deal to prevent trouble of a septic nature after the operation Cleanliness is the desideratum, and this is not by any means attained by the use of antiseptic agents Indeed, the best results have been obtained, not with the use of car bolic acid or corrosive sublimate, but by the use of distilled or plain boiled water Personally, I take it that the use of carbolic acid is never justifiable, for it can never be used in solutions sufficiently strong to possess aseptic properties without subjecting the patient to the danger of carbolic acid poisoning Where, however, septicæmia does present itself, it is best combated by reopening the abdominal wound and irrigating the peritoneal cavity with hot water The septic hyperpyrexia is best reduced by the administration of antipyrin, and when once the tempera ture is gotten within the safety line it is best kept In desperate there by the administration of quinia cases good results in the reduction of high temperature may be hoped for from the ice cap Stimulus must be freely given, and opium or chloral in sufficient doses to control the nervous disturbance which is nearly always present. Where it is necessary to give opium or chloral it is best to give by the rectum, saving the stomach for the administration of food and stimulus

Peritonitis following the operation is, I believe, generally septic in character, it is best subjugated by the use of salines Shock after the operation requires the same plan of treatment employed in treating shock after any other operation The usual dermic administration of cardiac stimulants, as soon ily killing many of the more common microorganisms as the patient can swallow a few spoonfuls of hot or paralyzing their development coffee, will generally be found the best means to counteract the shock

operation is justifiable for the relief of ovarian pain, is being made to determine whether the new princiotherwise uncontrollable, for the artificial establish- ple is an alkaloid or a glucoside ment of the menopause in cases of uterine fibroma

characterized by rapidity of growth and exhaustive hæmorrhage, and in which all other means have been tried unsuccessfully, for the cure of those cases of It is the duty of the nurse to count hystero epilepsy which have well defined menstrual exacerbations, and which have failed to yield to all other plans of treatment, and finally for those cases (which abound in every hospital for the insane) in which the mania or mental aberration is evidently dependent upon, or caused by, the act of ovulation Indiscriminate, or what may be called hit or miss spaying, cannot receive too severe condemnation

LETTER FROM LONDON

(FPOM OUR OW! COLRESIO (DF IT)

Density of Population—Uses of Embelia Ribes— Inhibitory Action of Cocaine in the Diagnosis of Neuralgias—Treatment of Carotid Hamorihage—Diagnosis and Treatment of Eczema-Carbolized Oil in the Prophylaxis of Scarlatina—Abscess of the Liver— Hot Baths in Hyarophobia

London, with all its millions, is not, after all, the most densely populated city in the country From the latest report of the Local Government Board, just issued, there is authority for the statement that the density of the population in the city of Liverpool as a whole, measured by the number of persons to the acre, is equal to 112, or double that of the me There are actually acres in which the population reaches 1,200 It is hardly to be nondered at that these are the home of typhus Much unwholesome property has been demolished of late years, but it is estimated that 60,000 persons are still living in wretched back to back court houses, around which free circulation of the air is practically impossible This estimate takes no account of frontstreet houses nor inhabitants of cellars houses are numerous cases of gross overcrowding Into this population immigrants from Ireland, where typhus is endemic, are constantly arriving, and it is to the temporary housing of these often semi-destitute newcomers that much of the overcrowding is due

The berries of the Embelia ribes, known in India under the name of Babarung, have been found by Dr W L Scott to contain several new principles, some of which are likely to become of great therapeutical and pharmaceutical importance is the name suggested in England for a principle yielded by these berries, which crystallizes in beautiful golden yellow scales It is said, although only very sparingly soluble in water, to act as an anthelmintic and germicide of a most powerful kind, speedalso partially examined these berries, and quite independently extracted therefrom a bright yellow scaly Further research alkaloid which he calls embeline

Dr Hurry Fenwick recently gave some interesting

inhibitory action of cocaine as a diagnostic factor in cases of neuralgic pain of the cranial, cervical, intercostal, renal, and lumbo sacral nerves Thus, with out a vesico rectal injection of cocaine, the leg of a decapitated frog was rapidly jerked out of a weak acid solution in a fraction of a second, but after cocame had been injected into the bladder or rectum, the leg was not withdrawn until after twenty to thirty seconds This inhibitory power was only observed when weak acid solutions were used Cocaine pos- per cent of pure carbolic acid, and he suggests use sessed no power of delaying the reflex excitability as soon as the rash is out over the whole of the body consequent upon stronger acid solutions lowing propositions were formulated nerve irritations, as neuralgias of any part, can be the treatment to be continued until the sixth week, relieved by injection into the urethra of a few drops by which time the desquamation is generally comof a 10 or 20 per cent solution of cocaine Severe nerve irritations, as the pain of carcinoma, Mr Fenwick has used etc, cannot be thus relieved this knowledge largely in the differential diagnosis of urinary disease Thus, if the renal pain was immediately relieved by cocaine, he judged the neuralgia to be due to a slight irritation, such as that experienced in lithiasis, congestion or grit If unrelieved he diagnosed more serious mischief, as stone, dilated He also drew attention to the value of cocaine in operations upon the bladder and urethra in preventing damage to an unhealthy kidney, and that the renal congestion produced by distending the bladder or injuring the walls, and this flooding of the kidney which, if the organ was damaged, led to rigors, suppressions and suppurations, might be wholly or partially prevented by the inhibitory action of co-caine upon the renal circulation Mr Fenwick gave also a long series of cases in which pain in various parts of the body had been temporarily relieved in 30 to 180 seconds by the urethral injection of a 20 per cent solution of cocaine

Mr Frederic Treves has devised a somewhat new plan for the treatment of carotid hæmorrhage when taking place from a small distant branch, as he considers the ligature of the carotid trunk was a severe, and often unnecessary method of treatment plan is to expose the artery and pass a thread of catgut round it, if the loop thus formed is pulled up, pulsation in the artery stops, if relaxed the circulation goes on again In four cases he has quite recently found this maneuver successful, and one great recommendation of the method pointed out to be, there are no grave risks from the operation itself, and in the four cases under his care there had been no local inflammation, nor had there been obliteration of the vessel

Dr T Robinson has just brought out a useful little work upon "The Diagnosis and Treatment of Eczema," in which he has annihilated the ideas of Mr Hutchinson, Sir James Paget and Dr Laycock Robinson considers that persons having an eczematous diathesis show a tendency to become bald or gray

demonstrations by means of decapitated frogs of the some the longitudinal flutings being evaggerated. As to the shape of the nail, it is often flat, sometimes even concave in its upper surface, frequently shaped like a shield, arcus senilis is also well marked as a rule in cases of eczema

> Mr I Brown, one of the provincial medical officers of health under the local government board, has drawn-attention to the prophylactic properties of carbolized oil in early and continued inunction in cases of scarlatina The oil he suggests cortains only 3. The fol- with the exception of the face The munction is 1 Slight used twice a day with a warm bath every night and plete

An interesting case of antiseptic incision in a case of abscess of the liver is recorded The patient, aged 30, being placed under the influence of ether, an incision about four inches in length was made half an inch below and parallel to the right costal margin, commencing two inches external to the linea alba, a dissection was made to the peritoneum which was cut though It was then seen that the upper surface of the liver was adherent to the diaphragm as far as the margin of the ribs, distinct fluctuation could befelt by passing one finger on the under surface of the liver and another on the lowest part of the thoracic The peritoneal wound was then closed with catgut sutures and a trocar passed through the adhesion into the abscess cavity The opening made by the trocar was gradually opened and ten ounces of pus evacuated The cavity was syringed with a solution of 1 in 5000 perchloride of mercury, the wound closed by catgut sutures and dressed antiseptically. On the third day the temperature was normal and at the end of a month the tube was removed, and the patient was well a few days later

Dr Buisson, of Paris, claims to cure hydrophobia by hot baths often repeated, he makes his patient remain continually in a hot room and the baths given are made as hot as 142°

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

New York County Medical Association—New York Quarantine Station-Hospital Saturday and Sunday Fund-Huason River Ice-Bequest to the Academy's Library—Bichloride of Mercury for Children

The annual meeting of the New York County Medical Association was held Monday evening, January 16, when the following officers were elected for diathesis show a tendency to become band of g. a, early in life, their teeth degenerate early, their incisors often wearing down and falling out. The nails tary, Dr. Frank Graner, Corresponding and Statistical Secretary, Dr. J. W. Small, Treasurer, Dr. C. Small, Treasure being pitted with small circular depressions, or in tee, Dr Charles A Leale On this occasion there

was an attractive discussion on The Diagnosis and Treatment of Pleural Effusions, which was opened by Dr Edward G Janeway, and among the other speakers were Drs J Lewis Smith and Charles A

After the repeated exposures that have been made of the many abuses existing at the New York Quarantine Station, it is seriously to be hoped that the Legislature will be sufficiently alive to the influence a valuable addition to its library, in the shape of about of public opinion, if not to a sense of their duty, to place the quarantine establishment on a business basis, to abolish its extortionate revenues, and to see that the contributions made by the public to secure its efficiency should be devoted under strict accountability to that purpose alone, and that its management his friend Dr John C Peters, with a view to turning be put into competent and responsible hands During the first few days of the session one or two meas ures providing for certain reforms in this department. which, strangely enough, emanated from the very quarantine ring which for years has been mismanaging its affairs for political ends, but, whether from distrust of the motives of their originators or some other cause, nothing has as yet been done to secure a business like and efficient quarantine management Yet the exigency is a pressing one. In the forcible language of Mayor Hewitt, in transmitting to the Governor and Legislature the report of the Commit-stated that the quantities of bichloride of mercury tee of the Academy of Medicine on their investigation of the quarantine station neither this city nor the State, nor any other portions of the Umon, are free from the dangers of the spread of contagious diseases unless the quarantine establishment at this port, under the control of the State authorities, is at once reformed and recon-The danger of delay is too imminent to admit of any postponement whatever"

The Presbyterian churches whose hospital this year, much to the regret of the other hospitals, and of many prominent Presbyterians also, withdrew from the Hospital Saturday and Sunday Association, seem to have made special efforts to secure large contribu tions for their institution, as it was recently an nounced that during and since the Christmas holidays the Presbyterian Hospital had received no less than \$31,000 Notwithstanding this withdrawal in subscrip tions to its funds, it was stated at the annual meeting of the Hospital Saturday and Sunday Association, which was held Jan 16, that the receipts reported from the annual collection were this season in excess of those of last year at the same date after the collection Up to Jan 18 the reported receipts had amount ed to \$45,725 The Roman Catholic and Presbyterian churches are the only ones that do not contribute to the funds of the Association, the aim of the managers of which has been to render it more and more unsectarian by the discouragement of designated offerings in their annual collection

In the light of the investigations reported by Dr Prudden in his paper read before the Academy of Medicine last year, there is reason to fear that consumers of Hudson River ice will next summer be exposed to greater danger than ever, since, owing to the lack of convinued cold weather, a larger quantity of ice than usual is been gathered from the upper of pressure is nil, and that therefore the effects, good,

Hudson, which receives the sewage of Albany, Troy, and other cities and large towns During the past autumn typhoid fever was so prevalent at Albany that the Mayor, at the request of the Board of Health, issued a proclamation urging the citizens generally to boil the drinking-water, which was believed to be the source of trouble

The Academy of Medicine has recently received 6,000 books that belonged to the late Dr Middleton Goldsmith, of Rutland, Vermont, formerly of this city, and one of the founders of the New York Pa thological Society The Rutland Herald states that Dr Goldsmith, feeling that death was near, wrote for his library, through him, over to the Academy had not embodied the bequest in his will, however, and his daughters, who were anxious to carry out his wishes, were told by their lawyers (their father being then unconscious) that in the absence of a verbal or written conveyance, the library would have to be sold with the rest of the estate They watched him anyously, and only a few hours before he died he recovered consciousness and said, in answer to an inquiry "Tell Peters to come on and get the books"

In order to prevent possible mistakes, it should be mentioned as safe to be given to children of various "It is evident that ages, in the notice of Dr J Lewis Smith's recent paper on diphtheria, published in The Journal of January 7, were meant not for a single dose, but for

administration during twenty-four hours

PBP

THE PNEUMATIC CABINET AND ITS CLAIMS

Dear Su -A recent discussion at the Academy of Medicine in New York, in which I had the honor of participating, showed such widespread misconception of certain facts of medical history and of physi cal law, that I desire to place on record in a journal that reaches the members of the profession in all sections of the country, some of the most serious of the objections which a number of physicians having no pecuniary interest in any form of instrument, but for many years extremely interested in promoting resort to pneumatic treatment as a powerful agent for good in the management of pulmonary diseases, and especially of phthisis, hold against the claims made for the instrument advertised as the "Pneumatic These objections are

I That the good or bad effects obtained in treatment of disease by modification of air pressure are due to that modification, and not to the particular apparatus employed, as a definite solution of morphine, for example, administered from a glass tum, bler, and the same solution of morphine administered from a silver teaspoon, have exactly the same effect

2 That, with the very moderate pressures employed in the pneumatic cabinet, which are all within ordinary barometric ranges, that is to say, within the ranges to which the organism is always in process of adjusting itself, the effect due to any absolute change

pressure between respired and surrounding atmos-

pheres

3 That, as the effects are thus due to differences of pressure (or "pneumatic differentiation"), it is a matter of indifference, therapeutically, by what mech-That, in other anism these differences are obtained words, supposing barometric pressure to be represented by 30 inches of mercury, the physiological, and therefore therapeutic effect of reducing the air about the patient to a pressure of 29 inches, while he breathes the ordinary (30 in) air, is exactly equivalent to the effect of increasing the pressure of respired air to 31 inches while the patient remains in the ordinary (30 in) atmosphere, the effect in either case being due not to absolute pressure, but to a difference of pressure represented in each instance by one inch of mercury In the same manner as the physical effect of "pneumatic differentiation" upon the mercury column of the gauge is identical in both cases, so the physiological effects upon a patient are identical in both cases

4 That the question of apparatus becomes thus simply a question of convenience and of expense

5 That, provided any apparatus permits the following four modifications of pressure, or any combination of them, it fulfils all indications, and the choice of instruments can be made by the physician, independent of any mysterious advantages alleged, but never demonstrated, for any particular apparatus

I Air pressure within the thorax at rest exceeds

atmospheric pressure—during inspiration

2 Air pressure within the thorax at rest exceeds atmospheric pressure—during expiration

3 Air pressure within the thorax at rest is less than atmospheric pressure—during inspiration

4 Air pressure within the thorax at rest is less than atmospheric pressure-during expiration

(We speak of the "thorax at rest" to exclude the effects of muscular movement and elastic traction, which are the same under similar conditions, independent of "pneumatic differentiation")

The first condition is fulfilled by inhaling condensed

air or rarefying surrounding air

The second condition is fulfilled by exhaling into rarefied an or condensing surrounding air

These facilitate respiration

The third condition is fulfilled by inhaling rarefied air, or condensing surrounding air

The fourth condition is fulfilled by exhaling into condensed air or rarefying surrounding air

These render respiration more difficult

6 That the pneumatic cabinet is less convenient than gasometer apparatus for the following reasons

The pneumatic cabinet, as ordinarily employed, combines the first and fourth conditions, and is ex actly equivalent to continuous respiration of condensed air with a double-cylinder Waldenburg apparatus, or one of its modifications, or to inhaling from a singlecylinder apparatus, and having the mask fitted with an expiratory resistance valve It is also possible to employ the cabinet with a combination of the second and third conditions, but, although other possibilities than these two are claimed for it they have never Treasurer

bad, or indifferent are due solely to the difference of been demonstrated in practice, and its most honest advocates frankly admit that they are not practical

> With the Waldenburg and similar apparatus, the following eight methods are both possible and practical, and have all been employed

A Any one of the four, alone

B First and second

C First and fourth

D Second and third

E Third and fourth

The most useful of all combinations are the first and second and the third and fourth, both practically impossible with the cabinet, as are also all of the single methods, which are often more useful than any of the combinations

7 The pneumatic cabinet is far more expensive than gasometer apparatus, which now range in cost from \$30 to \$90, and its use is thus restricted, while gasometer apparatus can be purchased by any physi-

cian and by many patients

8 In view of the recorded history of pneumatic treatment, and of the facts that the pneumatic cabinet is a "patented remedy", that it has no advantages physically or clinically over other apparatus, that it offers less mechanical facilities for variations of method, that the patient is shut away from examination and control during treatment or from prompt assistance in case of accident, that the cost of the cabinet is out of all proportion to the cost of other instruments, thus tending to prevent rather than promote the extension to all needing it of the benefits of this plan of treatment, we respectfully submit

9 That while those who prefer the cabinet upon commercial, æsthetic, or mechanical grounds are entitled to use and express that preference, they are not justified, either by recorded facts or physical principles, in claiming novelty or superiority for the instrument, its therapeutic methods or its clinical results, or in representing as the beginning and the end of the science of pneumo-therapy an instrument which is simply a comparatively unimportant incident in its

development

In thus endeavoring, in the interests of science and of humanity, to record the truth about a much beclouded matter, I have no desire to detract from any merit of which the history of their invention will show my friends Mr Ketchum and Dr Williams to be deserving, and, as I frankly stated in the discussion at New York referred to in the beginning of this letter, I think they are entitled to thanks for having, by their business push, given professional prominence to a subject to which their predecessors in the field had not succeeded in attracting much attention in America, outside of the city of Philadelphia I am yours very truly, SOLOMON SOLIS COHEN, M D

Philadelphia, January 20, 1888

THE AMERICAN PHYSIOLOGICAL ASSOCIATION WAS organized on Dec 30, in New York City, for the promotion of physiological research and of social intercourse among the physiologists of the country Dr H P Bowditch, of Boston, is the President, and Prof H N Martin, of Baltimore, Secretary and

NECROLOGY.

J F WAKEFIELD, M D

J F Wakefield, M D, the oldest physician in Everett, Mass, was born in Londonderry, Vt, June 20, 1825, and died at his residence Friday evening, His sickness was long and pain-January 14, 1887 This began with a serious attack of inflammatory rheumatism about two years before his death and its convalescent stages developed serious complications of the heart and liver, with dropsical These increased in intensity during the symptoms last year, accompanied with indications of blood poisoning, yet he bore it with a Christian fortitude, as those who were constantly with him can testify His cheerful, happy disposition robbed the sick room of its gloom until the last moments of his life

Dr Wakefield was beloved and respected by all those who had the pleasure of his acquaintance Those to whom he rendered professional services, his loss is felt as a personal bereavement, his pres ence brought into the sick room encouragement and hope, his kind offices to the suffering will remain a

pleasant recollection in many households

Dr Wakefield attended lectures and took his degree at Philadelphia Medical College in 1853, and at once came to South Malden (now Everett), to make this place his home and grow up with the people. It required courage for a young man, 28 years of age, to wait the slow process required to gain the confi dence of the community His untiring devotion to his patients was in later years rewarded by a large and lucrative practice No call was ever made for his services which did not receive prompt attention, oftentimes when he really was the one who most re quired professional care, and his visits in very many cases he well knew were gratuitous

His straightforward, manly course soon attracted the attention of his fellow townsmen, and offices of trust and responsibility were given him He was a member of Palestine Lodge of F and A M, was a charter member of Paladium Council, No 287, Royal birthday at Breslau Arcanum, and its Treasurer until within a few months of his decease, honorary member of the Legion of Honor, and its examining surgeon, also Treasurer of the Everett Associates, for sixteen years, resigning his trust only within a few days of his death, and was a member of Massachusetts Medical Society, connected with the Middlesex South District, an active and much respected member of this organization, having held the office of one of its Censors several years, and been one of its Counsellors at different He was a member of the American Medical Association since 1865 He enjoyed the fullest con fidence of this large and influential society of physi-

Dr Wakefield was a life long temperance man, attended the Congregational church in Everett, although an Episcopalian in religious belief In politics he was a stanch Republican

He leaves a widow whose love and devotion during his long weary months of suffering was rewarded by his grateful appreciation of her tender care, and

the kind offices so freely extended by neighbors and friends never failed to receive his warmest gratitude Thus passed from life, through death, into life beyond, this "good physician" The funeral services were held Monday, January 17, a private burial service at the house, after which public services in the Congregational church, the Episcopal clergyman officiating, after which Palestine Lodge of F and A M, conducted the impressive masonic burial service. He was buried at Woodlawn

MISCELLANEOUS.

BACII LUS OF CANCER —Some time ago Scheurlen announced in Berlin his discovery of a bacillus of cancer, which could be cultivated, and when inoculated on lower animals produced concerous growths On December 19, a letter from Dr Domingos Freire, of Rio de Janeiro, was read before the So-ciety for Internal Medicine of Berlin, claiming priority in the discovery, and showing that Scheurlen's observations are confirmatory of his own

ROLL OF PERMANENT MEMBERS — The name of Felix Formento, M.D., of New Orleans, La, was unintentionally omitted from the list published in THE JOURNAL of December, In the same published list the residence of Dr C B Powell is given as Attica, In, when it should have been Albin, In, and that of Dr J D Roberts, Goldsboro, N C, should have been Durham N C

THE TOKIO MEDICAL LIBRARY has now the largest collection of English books in Japan Most of them have been ob tuned by donation, and in the case of periodicals by exchange with the Sei I Kwai medical journal, the organ of the Sei I kwai, the Society for the advancement of medical science in Japan

EVULSION AS A MEANS OF RADICAL CURE OF PTERYGIUM

Read in the Section on Ophthalmology, Otology and Laryn gology, at the Thirty Eighth Annual Meeting of the American Medical Association, June, 1887

BY J W WRIGHT, M D,

Whether the limited amount of literature upon the treatment of pterygium is evidence that the highest degree of perfection possible in that direction has been attained, and that the various means proposed for its removal are all that can be desired, or that the subject is such as not to demand any special attention, certain it is, the methods employed for the removal of these morbid growths have been very unsatisfactory, and patients fail to receive such an assurance of benefit as it is desirable they should have

Although the affection is of little importance unless it implicates the cornea to such an extent as to obstruct the vision, yet its appearance to many, and especially to its possessor, is more or less repugnant, and patients are generally solicitous to rid themselves of its presence

Pterygium consists of hypertrophied tissue, often very trifling in amount, but sometimes very considerable and unsightly. This morbid growth is fibrous in structure and is not firmly adherent to the cornea and sclerotic. It is not covered with conjunctival tissue, but with an epithelial substance peculiar to itself which surrounds the hypertrophied mass, and is entirely disconnected from the conjunctiva, except at the linear adhesion on its under surface, where it acts in the manner of a pedicle

It seldom reaches or passes the centre of the cornea, for the reason, perhaps, that the blood-vessels which feed it do not extend further, usually, than that point

Without attempting to discuss the cause of this morbid growth, it is our object to consider the most feasible means for its thorough and permanent removal. Authors mention various methods for this purpose, which resolve themselves into three plans of operating, viz excision, transplantation and ligation, or a combination of two or all of these methods, thus, one recommends its entire removal by excision, by dissecting it from its apex to the semilar recommended the lunar fold, where it is excised, another recommends

dissection of the apex from the cornea to its base, and then inserting the dissected portion underneath the conjunctiva, where it is held by sutures, another advocates the ligation of the base and the dissection and excision of the apex, and finally, another the ligation of both the base and apex together with the narrow strip underneath the growth, where the ligatures are allowed to remain until the growth sloughs away. If any of these methods or any of their combinations have given general satisfaction, I am not aware of it, but, on the contrary, oculists usually discourage patients from having anything done with the affection unless it encroaches so far over the cornea as to interfere materially with vision

In a practice of more than twenty years, during which time I have attempted the removal of quite a number of these growths by one or another of the methods herein enumerated, I can recall but one case in which the result was all that could be desired, but, on the other hand, many of them were not benefited in the least, the operation frequently having resulted in unsightly cicatrices

Arlt has demonstrated that pterygium enters into the substance of the cornea, beneath its epithelial layer, yet, as previously mentioned, the connection is not firm, and its fibres can be readily separated from the cornea with very little effort

A few years ago, before the anæsthetic properties of cocaine were discovered, I attempted to remove a large pterygium in the case of a man who was somewhat under the influence of liquor. I caught the growth near its apex with the forceps. When I was about to separate it from the cornea with the scissors, he made a desperate effort at resistance, and caught my arm with which I was holding the forceps so suddenly that I did not have time to relax my hold. It bled freely, and I was fearful that the eye was badly injured. After a considerable time I was allowed to cleanse the eye, when I found that the pterygium was entirely separated from the cornea and as far back as midway between the sclero-corneal junction and the caruncula lachrymalis.

That part of the cornea to which the growth had been attached was somewhat hazy, and presented the appearance of numerous small depressions not larger than pin-points, showing the points where the fibres had penetrated the cornea. The patient would not permit me to proceed farther—not even to excise the

lunar fold, where it is excised, another recommends the eye and advised him to return daily, that I might

watch the eye He went home and, as he suffered am pleased to find a much better instrument for this no pain, concluded he was doing well enough, and did not return for three weeks, at which time the detached tissue had contracted and I could scarcely see any corneal opacity or other evidence that the eye had ever been affected with pterygium

What I so much feared in this case was that the corneal layers had been separated and, as a result, corneal ulceration, or, on the other hand, infiltration between the separated layers and a consequent ex-

tensive opacity

Subsequently I thought little of the occurrence more than to congratulate myself how fortunate I had been in not having destroyed the man's eye, until some time afterwards I was relating the circumstances to a physician, when he gave me the

following

An old gentleman of his acquaintance had a large pterygium on each eye He had been having his eyes "treated" from time to time by different parties, principally traveling "specialists," without benefit, when, in conversation with his family physician, he was informed that treatment in such cases was not generally successful, that his eyes would probably not Read before the Pleladelphia County Medical Society, on Janu become worse, and he was advised to desist

The old gentleman had his own idea about the matter, and insisted that the growth would continue to "cover the sight" and in a short time leave him hopelessly blind He argued that his disease was similar to that of the horse, known as "hooks," and that "hooks" are cured simply by "pulling them off" He concluded to act in his own behalf and, having procured a small pair of forceps, such as is commonly known as "eye tweezers," he actually removed the pterygia from both eyes, and without subsequent treatment the procedure effected a permanent cure

I have ascertained that the affection known as "hooks" in the horse is simply an attachment of the rational and useful membrana nictitans to the cornea, the adhesion being, probably, the result of an inflammatory action of this membrane and the ocular conjunctiva

Shortly after this, I presume about two years ago, I noticed in some medical journal that a foreign oculist, Arlt, I believe, was removing pterygium by evulsion, and being greatly interested, by reason of the circumstances just mentioned, I have been anxiously waiting to hear with what success So far I have been disappointed

For the past eighteen months I have used no other means in the removal of pterygium than evulsion As yet I have had only a few cases, but the result in

each has been eminently satisfactory

In my first operations I removed the apex, and as far back as the caruncula lachrymalis with the forceps, and excised the loose tissue with the scissors Afterwards I ligated the base first and then removed the growth with the forceps as far as the ligature, and excised as near it as possible In this I found a great advantage, masmuch as the ligature prevented hæmorrhage and I could operate to a better advantage

the forceps, and took in its stead a blunt hook—such gymnastics, particularly systematized active everas is used in the operation for strabismus—which I cises Masseurs and masseuses, good, bad, and

purpose

After the base has been ligated the pterygium is separated from its attachment with the blunt hook, by running it under a small portion at a time, especially if the pterygium is large, first separating the thin connection between the ligature and the cornea, then a small portion of the corneal attachment at a time, until the whole is removed

The loose tissue is excised as close to the ligature as possible, cold water dressings are used, and the ligature is allowed to remain until the strangulated portion sloughs, when it, with the ligature, will be-

come detached and pass off

The advantage of this operation is the complete and thorough removal of the growth from the parts into which it has been imbedded, without the injury or superfluous removal of any normal tissue

THE TREATMENT OF NERVOUS AND MENTAL DIS-EASE BY SYSTEMATIZED ACTIVE EXERCISE

ars 11, 1888

BY CHARLES K MILLS, MD, OF PHILADELPHIA, PA

Exercises or movements for medical purposes, medical gymnastics, in other words, have been divided and subdivided to an absurd degree by Ling and his followers Schreiber gives an example of a German term for what is called the quarternary combination of the standing position, which term contains forty-five letters and nine different words, although it is written in German as a single word The division, however, into such movements or exercises as passive, duplicated active, and active, is Passive movements are performed upon the patient or individual, his will not coming into play except in submitting In duplicated active movements, both the operator and the individual treated, take part, the first resisting while the second acts, or the reverse Sometimes these movements are spoken of as semi-active and semipassive, in the former, the physician or operator resists, in the latter, the subject resists Movements of this class are of the greatest value in some forms of nervous or neuro-muscular disease, but it is not my purpose to discuss them, unless it be incidentally, in this paper, nor do I intend, except perhaps in the same manner, to speak of massage

It is of systematized active exercises, that I will The expression single acmore particularly speak tive movement indicates that the movement is performed by a single individual without direct assistance, although it may be done under the orders of a physician or master Exercise of this kind may be performed either with or without apparatus, and even when the latter is used it need not necessarily be expensive While massage and electricity have Recently, at the suggestion of Dr Baldwin, of this received a large share of attention from neurologists, city, while assisting me in an operation, I discarded they have neglected too much the use of medical

indifferent, now abound in our large cities, but good instructors in physical culture, as applied to medical

purposes, are not numerous

"Gymnastics," "evercises," and "movements," by some medical writers are used as practically synony-Dr George H Taylor, however, claims that we should carefully distinguish between gymnastics and movements, and between calisthenics and movements, and that evil has grown out of confounding paper to speak with precision of "movements" or "exercises," designating the particular kind, but "medical gymnastics" covers the whole ground, and the word "gymnastic," or "gymnastics," used in a general sense, may be properly employed in medicine

I will not give much space to a discussion of literature, but will refer briefly to a few important publications, including those which I have chiefly

consulted in the preparation of this paper

The attention of the profession of this country has been too little attracted to the publications, and the practical work of the brothers, Dr George H Taylor and Dr Charles Fayette Taylor, of New York, who may be regarded as the pioneers in this country of the gymnastic treatment of disease They deserve great credit for their efforts, not wholly ap As early as 1861 a book was issued on The Theory and Practice of the Movement Cure, by Charles Fayette Taylor, M D, in which is discussed in an interesting and practical way, the treatment by Swedish movements, of curvatures, paralysis, indigestion, constipation, diseases of women, etc 1879 appeared a treatise entitled An Exposition of the Swedish Movement Cure, etc., by George H Taylor, AM, MD Dr Benjamin Lee, of Philadelphia, by his practical labors, and his publications on massage and Swedish movements, has done much to advance the cause of mechano-therapy in America, and stands with the Taylors as a pioneer in this department

Archibald Maclaren's System of Physical Education, Theoretical and Practical, is an invaluable book. be studied by every physician interested in active pulley-weight apparatus exercises as a means of treatment Blaikie says truly of Maclaren, that he has done more than anyattain these benefits By his individual efforts and and for the sketch of a pair of pulley weights of exhis publications, William Blaikie himself has also done a great work for the advancement of physical His book published by Harper & Bros, in Stay So, has enlisted the interest of thousands, and doubtless has lengthened or saved many a life 1886 appeared another little work by Blaikie, in the form of a school text-book Sound Bodies for Our Boys and Girls The exercises given in this book are clear and plain, they are arranged on a natural plan, they are safe, and but little apparatus is resticks, and a horizontal bar, are about all I have performance of many movements found them to be admirably suited for my purpose in the treatment of some forms of nervous and mental disease

In the Therapeutic Gazette for June and July, 1887, appeared two lectures by Professor Dujardin-Beaumetz, of Paris, in the first of which he considers the physiological effects obtained from exercise and movements, and in the second, after setting forth the methods of medical gymnastics, he discusses the diseases and condition in which they are useful

A Manual of Treatment by Massage and Methese terms It is probably better in a medical thodical Muscle Evercise, by Joseph Schreiber, M D, of Austria, translated, with the author's permission, by Walter Mendelsohn, M D, of New York, has appeared within a few months This book treats the subject of mechano therapy from various points of view, and in it are found explicit directions in regard to the technique of massage and its effects, and also a discussion of active movements with and without The treatment of many nervous dis apparatus eases is discussed. The book is a valuable practical treatise, and its publication will do much to advance mechano therapy in this country, but one of my chief reasons for referring to it is because it contains an extensive chronological bibliography, which can be consulted by those interested

> I am engaged in the preparation of a book on the Gymnastic Treatment of Nervous and Mental Discases, in which will be considered both general and local methods of exercise, and the combination of such methods with other forms of treatment, as for instance, with massage, electricity, hydrotherapy, and medicines

One of my chief purposes this evening is to call attention to general systematized active exercise I will also speak of a few special or local exercises designed for particular organs or parts In a large number of nervous and mental cases, the improvement of general nutrition is the one thing needed to bring about relief or cure, and one of the most effective aids to this end is general, systematized The methods chiefly adopted by active exercise me are (1) the exercises of Blaikie, with or without dumb bells, and with the horizontal and parallel bars, and while not intended for medical purposes should or substitutes for them, and (2) exercises with

I need only refer you to Mr Blankie's best known book for a description of some of the simplest forms one else now living to point out the benefits result- of apparatus, to the uses which can be made of the ing from rational physical exercise, and how to jambs of a door and a couple of pitchfork handles,

cellent pattern designed by Dr Sargent

A J Reach & Co, of Philadelphia, the well known dealers in sporting and gymnastic goods, have con-1883, and entitled How to Get Strong and How to structed a form of pulley weight apparatus, which is

very complete, compact and convenient

"The Home Exerciser" of C L Dowd, of New York, is also convenient and useful, and has been strongly endorsed by Mr Blaikie for its compactness, strength, lightness, etc The apparatus of Reach and Dowd consists of an arrangement of ropes, pulleys, and weights, ingeniously put together quired for them-a few dumb-bells, a few wands or so as to occupy but little room, and yet to allow the

"The Home Gymnasium" of John E Ruebsam, of

¹ How to Get Strong etc

Washington, D C, is well adapted for the office of insane department of the Philadelphia Hospital a physician, or for hospitals and colleges For a long time I have had this apparatus in use It occupies more room than the apparatus of Reach or Dowd, but, on the other hand, it is in some respects more complete, having, for instance, combined with it a lounge for massage purposes, and a strong horizontal bar An apparatus of this kind or one similar should be in every hospital which has not a complete and experienced instructor and expert in gymnastics gymnasium

Elastic straps are sometimes used for gymnastic According to Dujardin-Beaumetz, Pitch ery was the originator of this system, which he has styled "opposition gymnastics" Elastic cords with handles attached are firmly fastened in convenient By making tractions in different directions, they will bring out almost any muscular action can be adapted for the leg or foot movements, as well as to the upper extremities Some objections, however, apply to them which are not applicable to the pulley-weight apparatus, or to the use of dumb bells, The force used cannot be thoroughly bar bells, etc controlled and regulated Blankie in describing and criticising one of the forms of parlor rowing apparatus, has pointed out their defects and shortcomings better than can be done by myself In spite of their defects, however, he considers them his patients if he cannot become interested excellent contrivances, if used intelligently

Movement apparatus run by steam has been largely resorted to in some countries, particularly in lar and respiratory," says Maclaren, "depends the Sweden, where the method was invented and introduced by Zander In this country, it has been used nervous force has also something to do with the cain a few institutions, as at the Surgical Institute, formerly located at Broad and Arch Streets, in Philadelphia, where I have observed its workings The system has a field of usefulness, it has also certain disadvantages, and needs the most careful supervision, but under the strictest supervision, it may be used with great benefit To some extent, semi-active and semi-passive or duplicated active movements breaths through the nose and mouth, by forced exmay be carried out by this machinery, and it can be made to cover the whole range of passive exercises

The same cautions and contraindications are to be borne in mind in using the exercises either with or without apparatus probably the dangers of overdoing are to some extent greater with than without apparatus In the prolonged treatment of patients, some advantages accrue from the use, conjointly or alternatety, of exercises with and without apparatus The interest of variety is added, and the opportunities of the adaptation of movements to special cases and conditions are more numerous Most of the firms which sell pulley-weight apparatus send with them printed instructions and illustrations, but I must enter a word of caution against the employment of such apparatus by invalids without special medical supervision Much harm has come to individuals, as well as to the subject of medical gymnastics, by the use of exercises without specific directions

To a considerable extent, I have personally directed the exercise-treatment of my patients in private practice, and in the nervous wards and the

A H P Leuf, instructor in physical culture in the University of Pennsylvania, and Dr O H Beckman and Dr Mary Willits, assistants in the department of the mind and nervous system in the Philadelphia Polyclinic, have, under my instructions. successfully treated patients for me

Mr Clinton A Dodge, of Philadelphia, is an able During the present year he has treated for me, with marked success in most cases, patients suffering from neurasthenia, hysteria, habit chorea, neuritis, lateral spinal curvature, melancholia, etc Dodge has also had under his charge the patients of other physicians, and, by their permission, he has given me some of the results of his work

The director of these exercises should be thoroughly well fittted for his work He should not only understand the work, but he should combine discretion with enthusiasm in pursuing it. If not a physician, or if a physician without special experience in such work, the treatment should be carefully supervised by some one more competent treatment should be carefully individualized instructor or director should not undertake too much in one day, and he will soon tire and do badly with

Usually I combine respiratory exercises with the "On the two powers, muscumuscular movements ability to perform all bodily exercises" Inherent

pacity to perform bodily exercise

Of course, in any method of gymnastics, respiration must to some extent be exercised becomes accelerated, and even painful, under continuous active exercise In speaking of respiratory gymnastics in this connection, however, I refer to special efforts of breathing-by taking deep, full piration, as well as inspiration, by counting with a loud voice while holding the breath, etc It is not my purpose to refer in this paper to the use of pneumatic chambers or other forms of pneumatic

It is interesting to recall that the most ancient of books in which gymnastics is discussed, the Chinese Treatise Cong-Fou, the Art of Man, speaks particularly of the importance of respiratory gymi astics Dally and others in the present century, have maintained that respiration is the pivot of every gym nastic exercise, and systems of respiratory gymnastics

have been invented (Dujardin-Beaumetz)

Want of respiratory power is certainly either at the root, or is an essential constituent of many morbid nervous conditions It is remarkable how much individuals differ with reference to their respiratory power, even when of apparently the same muscular The development of the lungs, chest walls, diaphragm, abdominal walls, and other parts, the greater aeration of the blood which is conveyed to weak spinal or encephalic centres, the greater cortrol which the patients obtain over all nervous and muscular effort through these respiratory exercises,

make them of decided value in cases in which active up high all the time movements are applicable On the other hand, it is quite possible that some harm may result from the incautious use of forced respiration Curried on too long, both as far as giving lessons is concerned, and as far as the weeks and months during which the exercises are continued, it is even conceivable that the air-cells may be unduly strained Great care should be taken with those who are very weak generally or in a particular part, especially in the lungs or abdominal region

The treatment should begin with the simplest forms of exercise, and these should be constantly increased and elaborated, as the patients gain in skill and It is wonderful how little some patients A grasshopper in gymnascan do in this direction Five minutes, or even less, tics is a burden to them is sometimes all the time that can be safely taken at first, and five minutes of actual exercise must sometimes be distributed over half an hour In most cases the time should never be allowed to exceed twenty or thirty minutes Often it is important to give resting spells during the process of treatment Some patients, ambitious to excel or fearing to appear weak, will certainly overdo Individual peculi-arities should be carefully studied In the majority of cases of nervous and mental diseases in which systematized active exercises are indicated, the danger will be greater of overdoing than of doing too

It is an important practical matter to have the air of the room in which the exercises are performed as pure as possible The room should be well venti-It is not necessary, particularly in the case of the nervous and weak, that the room should be without fire, indeed, it is sometimes better that there should be some warmth, but fresh air should be admitted to the room

When possible it is well for the patient, soon after finishing the exercises, to take a sponge bath, with tepid or cold water, according to individual Good food, regulated exercise in the open air and plenty of sleep are, of course, important

To illustrate clearly what is meant by simple respiratory exercises in connection with systematized muscular movements, I will quote for you from Blaikie's smaller work two of his very plain directions I will also quote from the lectures of Dujardin-Beaumetz one of Dally's movements

"Directions - I Stand four feet apart in the aisles, with arms folded behind you, and with one foot about eight inches in front of the other 2 Now draw the head back and tip it as far down behind as you can Hold the chin up high 4 Rest there a moment, then stand up straight again 5 Repeat this exercise six times

"Caution - Breathe deep, full breaths all the time, indeed, always, when evercising, breathe slowly, and as large breaths as you can "

"I Take a dumb-bell in your right hand and hold it up high over your head 2 Stand with the chin

3 Breathe a full, deep, slow 4 Now slowly lower the dumb bell, not down to your right shoulder, but across, above your head, and down over your left shoulder, as low as you can, till it touches your shoulder, letting your body tip over to the left 5 Hold it there till you 6 Now bring it back overhead slowly count ten Then do the same with the dumb-bell in your left hand 7 Do this five times with each hand

"Repeat this five times each day the first week, and twelve times daily after that right along"

One of Dally's respiratory exercises is as follows He places the patient in a vertical attitude with the back against a wall, then, both arms being extended horizontally in front, the patient forcibly and slowly separates the fingers while he bends the thorax forward, he remains in this position thirty seconds, makes a deep nasal inspiration, and resumes the initial position, then makes a deep expiration, and repeats this exercise six times in succession

Dujardin-Beaumetz, in reference to these exercises of Dally, remarks that another and simpler exercise will render much service in developing respiratory capacity, viz to make the patient count with a loud voice as long as he can without losing breath Before commencing to count he should make a deep nasal inspiration

Among the diseases of the nervous system referred to by Dujardin-Beaumetz as calling for gymnastic treatment are muscular atrophies, deformities, chorea, hysteria, ataxic, nervous, and neurasthenic persons, the victims of mental overwork and sedentary life, He also discusses the uric acid diatheand idiocy sis, gout, and diabetes, for which the neurologist is often consulted

This paper is not founded simply upon theoretical considerations and a study of literature For several years I have to some extent used systematized active Carrying out strictly hygiene in various directions exercises, either with or without apparatus, and durwill very much assist in getting good results with the ing a year past I have had a considerable number of patients on this treatment My objects, in addition to recording experience, are to call general attention to a too much neglected method of treatment, and to make certain practical suggestions which naturally grow out of a study of the subject It will be impossible to give details of cases without dragging the paper to a wearisome length When preparing this paper I was able to put my hands on forty-two such cases, not including those under treatment at the Of these cases, twenty-five Philadelphia Hospital were treated by the general active exercises, some with and some without pulley-weight apparatus, the other seventeen by some local method for a special The patients treated by the general exerpurpose cises included cases of idiocy, insanity, asthma, minor chorea, habit chorea, hysteria, general nervousness, neurasthenia, nervous palpitations, lithæmia, cerebral syphilis, diabetes, curvatures, ataxias and paralysis, those treated by special more or less local methods included cases of hemiplegia or monoplegia, ınfantile paralysis, lead paralysis, rheumatic neuritis, muscular atrophy, aphonia, and writer's or telegrapher's disease

For the feeble-minded, for the insane, and even for

criminals, systematized active exercises can be used in a great measure, and the refractory wards, with with great advantage Those in charge of institutions for the idiotic and feeble-minded in France with patients, attendants holding them down, and have in particular given much attention to gymnas- removing them into the seclusion of their own rooms, Esquirol, Bourneville, and Pichery At the Pennsyl-|system to patients and guardians, but I believe the vania Training School for Feeble-minded, at Elwyn, risks are much less in reality than under the old sysin charge of Dr I N Kerlin, I have frequently, and tem, for the patients are not so irritable, not so rewith great interest and pleasure, witnessed the performance of the gymnastic classes As many as eight separate classes are instructed at one time by as be provided with an additional "rational physiological many teachers, and at intervals general exhibitions outlet" for their morbid muscular energy, on the one who can only perform the simplest movements, up to method of calling them out of their muscular and those capable of elaborate and somewhat difficult ex-At Barre, Mass, a gymnasium has been erected, and the children are thoroughly drilled and The same is true of some other institutions for the idiotic and feeble-minded in this country Much could be said, if time permitted, about the beneficial effects of regulated physical culture in For the improvement of the general nutrition of a class of unfortunates usually deficient in this respect as well as for their training and development, both mental and physical, systemic exercises are of the utmost value In some of the grades of idiocy attention should be paid to individualizing the tence, be aroused to the performance of some movetreatment by exercise To a certain extent gymnastics can be used for diagnostic and prognostic purposes in idiocy, observation of those attempting systematized exercises determining the possibilities has been clearly shown. The class has made much as to general improvement

So far as I know, very little has been done with systematized movements in hospitals and asylums for the insane, although I believe insanity affords a great field for such treatment In the first place, such exercises will do much toward improving the frequently young man who, at the age of 21, broke down mendeteriorated physical condition of the insane, secondly, they afford a method of calling out and improving the impaired mental faculties, and thirdly, they constitute another valuable means of supplying | believing that people were watching and following to the insane that which all alienists now agree is him most important for them—occupation

"One of the great improvements that has taken place in modern asylum management," says Clouston,3 "has been that rational physiological outlets are provided for the morbid muscular energy in cases of They are neither confined in their rooms, nor within 'airing courts' enclosed by high They are made to wheel barrows and dig on walls They are encouraged to dance, and are well Most of them eat enormously, and if they have not enough to eat they fall off, get worse in their mental state and in their habits Many of them can be got to expend their energy in hard, regulated work, and are the very best workers on the farms and in the laundries of the asylums They are not all, of Some of them simply course, furiously maniacal have a slight morbid excess and exaltation of the attacks, and he has been entirely without the regular brain convolutions, shown by restlessness, want of periods of depression and elevation for nearly three affection, want of self-control, but are not incoherent If they are kept at work the most objectionable and

their noise and danger, are not needed The scenes It is only necessary to recall such names as are few. No doubt there are risks run in the present vengeful, and not so dangerous generally

By means of systematized exercises the insane can The classes are graded from those pupils hand, and, on the other, with a rational physiological

general torpor

A few weeks since, in the Insane Department of the Philadelphia Hospital, I started a class in systematized active exercises, selecting eight women suffering from melancholia, and putting in with them to give zest to the treatment two other cases not mentally depressed Sufficient time has not yet elapsed to determine how much in a curative way can be accomplished by such treatment, but already the experiment has proved to me an instructive one I found that even these patients, plunged into the profoundest depression, could, by sufficient persisments, others did moderately well, some very well The difficulty of fixing the attention of these patients, and yet the possibility of doing it by sufficient effort improvement in facility and rapidity Small classes should be formed in large insane asylums, and the system given a thorough trial

An instructive case of mental disease greatly benefited by systematized active exercises, is that of a tally, as the result of too great output of mental energy and physical evertion in business He became depressed, and soon developed delusions of suspicion, In a few weeks, under rest, the depression disappeared, he again attempted business, but became excited, and then developed ambitious delusions He was admitted to an asylum for the insane, and in three months came out, apparently well his subsequent history for eight years was that every year, late in the spring or early in the summer, he had a period of excitement, followed by one of de pression, each lasting about three months three years ago he began the use of systematized active exercises, after the method of Blaikie and He has since persevered with them, at the others same time paying attention to diet, sleep, and general hygiene On a few occasions he has had touches of elation, lasting only a day or two, but he has been able, owing to his increased physical and mental strength, to resist with success the beginnings of such

An experiment made at the New York State Rerepulsive parts of the older asylum life are avoided formatory, at Elmira, has been frequently referred to of late by the medical and general press An ex-

⁸ Clinical Lectures on Mental Diseases, p 158

twelve men, who for a period ranging from one to power of compensation, and is better in regurgitation two years, had made no appreciable progress in their school work, and who seemed incapable of prolonged mental effort, yet could not, strictly speaking, be other form of cardiac disease, and the prognosis is considered mentally unsound, or representatives of a class known as feeble-minded, with the object of ascertaining, if possible, if physical culture, as comprised in frequent baths and massage, and daily calisthenics under the care of a competent instructor, would not result at least in the partial awakening and stimulation of dormant mental power Increased mental activity rather than muscular development was to be the gauge of success or failure of the experiment

Dr H D Wey, physician to the Reformatory, in reporting the results of the experiment, says that to those who are thrown in daily contact with the men, a mental awakening was apparent They became interested in their studies and strove to appear to the best advantage in the school-room Their advancement in their studies was not steadily onward, but rather in-It will be interesting to termittently progressive note in the future, as Dr Wey remarks, whether the good results are permanent, but whether they are or not, the step is one in the right direction, and is to be commended to penologists everywhere

(To be concluded)

PROGNOSIS IN VALVULAR LESIONS OF THE HEART

Read before Chicago Pathological Society, December, 1887 BY JOSEPH M PATTON, M D, OF CHICAGO

The most interesting question in connection with cardiac valvular lesions, and one that requires the most accurate knowledge of the physical condition of the heart, and of the changes that have taken place, and of those which are yet to follow, is the question of prognosis

The incurability of organic disease of the heart, confines the management of these cases to one object, namely, how long can the heart be made to perform its function? To this end it is necessary that an inpoints First The seat of the lesion and its character Second, The physical changes already effected by the lesion Third, The histological changes resulting from these altered physical relations

The careful study of these questions, and of the liability to further changes, both physical and pathological, in which any or all of the above-named conditions may be factors, will enable us to make a reliable and scientific prognosis The effect of location on the prognosis depends on the time of life at which the trouble begins, and on the character of the lesion

In early life the mitral valve is generally the one at fault, and the lesson is most often regurgitant is due to the fact that mitral disease in young subjects is generally secondary to acute endocarditis, and to the high blood pressure on the under side of these

perimental class in physical culture was formed of valves. The prognosis in these cases depends on the than in stenosis Mitral disease at middle life, or subsequent thereto, is generally secondary to some

> Disease of the aortic valves generally occurs in adult life, probably owing to the tendency toward inflammation of the aorta, immediately around the sinuses of Valsalva, during this period

> The prognosis here is better in stenosis, than in regurgitation, aside from the liability to cerebral embolism, which Niemeyer limits to cases of regurgitation, I believe that embolism is not of very frequent occurrence as I have met with only one instance, and that in a case of stenosis in a girl 12 or 14 years

> Second, as to the physical changes in the heart effected by the lesson And in this connection cardiac hypertrophy is not to be considered as a diseased condition, but as the necessary and only remedy which Nature can give to a pump whose power is being overtaxed by reason of a faulty valve

In mitral regurgitation there is first dilatation of the left auricle, but this is generally slight, as the intra-auricular pressure is not very much augmented The increased pressure in the pulmonary circulation is immediately relieved by hypertrophy of the right ventricle, which is a simple hypertrophy, and not eccentric, as is generally stated When this compensation takes place the prognosis is good, and remains so until the hypertrophy becomes eccentric from degeneration of the right ventricle The muscle being no longer able to withstand the increased intra-ventricular pressure, the prognosis then becomes grave The increased pressure in the left auricle and pulmonary veins throws the blood into the left ventricle with more than usual force, hence there is slight dilatation and hypertrophy of this ventricle, which equalizes the arterial circulation In some cases complicated by extensive myocarditis, dilatation of the left auricle, and ventricle, may be so rapid that the patient dies before compensatory hypertrophy can be obtained In a recent case of this nature in a child 8 years old, the heart muscle was very weak telligent prognosis be made, based on the following from myocarditis. The patient was very anæmic, yet under treatment the improvement was very slow, but steady for several weeks, when, after taking a long walk and overtaxing the heart muscle, rapid dilatation took place and the child died in a week or ten days

In mitral stenosis there is dilatation of the left auricle from the increased pressure necessary to force the blood through the constriction, and though the right heart compensates for the obstructed pulmonary circulation, the prognosis is rendered more grave than in regurgitation, because of the over-distension of the left auricle, which is but moderately supplied with muscular tissue, and is unable to withstand 1t

In aortic disease the left ventricle furnishes the compensating power In stenosis, its first effect is hypertrophy of the ventricle This fully controls the interference with the blood current, and all goes well so long as the muscle retains its integrity

⁴ Annual Report of the New York State Penttentiary, at Elmira, for the year ending September 30 1886

The prognosis at this stage is good, as a patient may remain in this condition for many years, totally ignorant of any cardiac trouble Sooner or later lowed by dilatation of the organ, by reason of lessmuscular degeneration sets in, as evinced by ven- ening of the resisting power of its muscle tricular dilatation, as the muscle is now no longer able to withstand the blood pressure, and as the dilatation becomes advanced the mitral ring is stretched, insufficiency of that valve results, and this gives an obstructed pulmonary circulation at a time when muscular degeneration prevents compensation by the right heart, therefore, as soon as mitral regurgitation occurs in these cases, the prognosis gets grave

In aortic regurgitation the first effect is dilatation from the direct force of the reflex current impinging on the walls of the left ventricle while it is relaxed, also, from overdistension by the addition of the regurgitated blood to that normally received from the tion of only a short time until asystolism of the heart This is followed by hypertrophy, The prognosis at this stage is which is eccentric not as favorable as in the same stage of stenosis, that is, when compensation is obtained, for the reason that in stenosis when the hypertrophy has fully overcome the obstruction at the valve it may remain stationary so long as there is no change at the valve, or in the integrity of the muscle, while in regurgitation the distending force is constantly present, and the hypertrophy must be progressive It is for this reason that we find such immense left ventricles in some cases of aortic regurgitation As soon as the hypertrophy fails to arrest the dilatation, mitral regurgitation ensues, as in stenosis, but is reached in much less time, as a rule, hence the prognosis is even more unfavorable than in the same stage of aortic stenosis

The statement made by some authors that hypertrophy of the right heart in disease of the left side, and of the left ventricle in aortic stenosis, is eccentric, I believe to be erroneous Niemeyer claims that simple hypertrophy is rare, and only obtained in such interference with the circulation as is given in Bright's disease or chronic asthma, or bronchitis I do not recognize any difference between the effect on the left ventricle from the increased vascular pressure in Bright's disease, and the effect on the right ventricle in pulmonary obstruction from mitral regurgitation, or on the lest ventricle in aortic stenosis before degenerative changes begin

Histological Changes — This consists in the hypertrophy of the muscular tissue, which results from the increased nutrition to the heart muscle, as demanded by its extra labor, similar to like changes in other muscular tissues under like circumstances I believe this to be a simple increase in volume of the primitive muscular fasciculus, and not a numerical increase This increase in volume of as is claimed by many the fasciculus may be caused by swelling of the sarcous elements of which the fibrillæ are composed, or possibly, increase of the number of fibrillæ within the sarcolemma, if there were actual increase in the is not so dangerous as in mitral regurgitation, hence number of fasciculi, with their investing sarcolemma, there would also be increase in the number of muscular bundles with their perimysium, and after degeneration of the muscular fibre this would leave an excess of the areolar tissue of which the perimysium is com-This I have not been able to see posed

The pathological changes taking place are those of degeneration from defective nutrition, and are fol-

The interference with the coronary circulation by reason of the physical changes in the heart by atheromatous degeneration of the aorta or coronary arteries by inability of the arteries to carry enough blood to supply the increased volume of muscle, causes a fatty degeneration of the primitive muscular fasciculi The endo cardiac blood pressure now exceeds the contracting power of the muscle and rapid dilatation follows

The prognosis then, in a heart that has been hypertrophied, becomes grave with the appearance of symptoms indicating dilatation, for now it is a quesis developed, and under such conditions the heart cannot long perform its function

A word as to the danger of sudden death from organic disease of the heart I do not believe this danger is sufficiently imminent to warrant us in placing it among the elements of an unfavorable There is no influence in the heart, per se, prognosis tending to cause sudden cessation of its action Cerebral embolism, it is true, may cause sudden death, but this, as already shown, is not frequent

The formation of a ventricular clot from healthy blood is not possible, except when the heart has developed asystolism, in which case the prognosis is already rendered grave, because of the physical condition of the heart I have never seen a sudden death from organic heart disease where the diagnosis was assured and the cause of death referable to the And were the actual cause known of the many sudden deaths which are laid at the door of this hardworking and long-suffering organ, I believe the vast majority would be found due to causes extraneous to the heart, probably some circulatory disturbance, or tissue degeneration of the nervous centers, causing a lack of the proper innervation of the The fact at least remains, that in organic heart disease of the heart sudden and unexpected death is a marked exception to the general termination, and if this be true in diseased conditions, what cogent reason can be given for attributing sudden death to the heart, in persons who have never given any evidence of cardiac disease

From the foregoing we would derive the following

The prognosis when compensation is obtained is better in aortic stenosis and in mitral regurgitation than in aortic regurgitation, or mitral stenosis person with either of the former lesions, moderately severe and fully compensated for, may live 20 or 30 years and suffer no inconvenience therefrom

In aortic stenosis intercurrent disease of the lungs the prognosis in the former is somewhat better

In aortic regurgitation, and in mitral stenosis, the prognosis is not so good, because the eccentric hypertrophy in the former, and the dilatation of the left auricle in the latter, renders perfect compensation difficult

The more pronunced the lesion the more grave the prognosis, in direct proportion to the increase in intra cardiac pressure

Double lesions at one valve, or two distinct lesions at different valves, which have begun at the same time, render the prognosis grave in direct proportion to the increased liability to dilatation of the different cavities

SALICYLATE OF AMMONIUM FOR FEVERS

BID M WICK, MD, OF NEW HARTFORD 10% A

Last winter, in February, I was treating L P, a boy of 6 years, for remittent fever, the temperature varying from 102° to 103° I began with the classic al course hydrarg chlor mitis to arouse the secre tions, quinine as an antiperiodic, and veratrum and sp's with nitrosi as a febrifuge. At the close of the second day of treatment, he broke out on face and neck with a bright scarlatinoid eruption, resembling very much that of scarlet fever The parents be came greatly alarmed, fearing that the boy had scar-Assuring them that he had not, and that the eruption was caused by the powders, I continued the same treatment The next day the eruption was still more diffused over the whole surface of body. with intolerable and incessant itching and fever as high as at first visit For another day (the fourth) the same treatment was persisted in, only to aggravate the erythema, cause cedema of face, hands and feet, and with the itching, that had persisted from the first appearance of the quinine exanthem, made my little patient more restless and miserable The fever had now increased to 103° morning and 104° evening I had never used salicylate of ammonium, but thought this would be an opportunity to test its value as an I had read the papers of Drs Jackson, antipyretic Barnett and Sullivan Leaving off all the former medicines, I dissolved 5ss salicylate ammonium in 511 aquæ and ordered i teaspoonful every two hours

I saw the patient again in eight hours, and found him with temperature reduced to 99 5°, resting quietly and sweating profusely Continued the dose the same and lengthened the interval to four hours Next day the temperature was normal, tongue becoming clear, eruption disappearing, and the boy feeling so well that he wanted to be up and dressed He made a rapid recovery

been sick nearly one week when first seen him on the orthodox treatment, and continued it one week, during which time his fever was never below 102° nor above 104° He had a hot, dry skin all the time

I again dropped all other drugs and gave salicylate of ammonium, gr 1j, in water every two hours In about eight hours his temperature fell to 99° and he was bathed in perspiration Continued the dose once in four hours Saw the case next day and and was soon able to be around

May P, a girl of 11 years, had measles The disease pursued its usual course and the eruption receded as in other cases But the fever, which had ranged high throughout (from 102° to 104°) continued An active diarrhoa set in, her tongue was dry and heavily coated, and sordes was on the teeth She was now in a semi-delirious condition, with a temperature of 105° I had no trouble in controlling the boxels with mineral acids and small doses of opi-Despite the frequent bathing, quinine, gelsemium and aconite, the fever kept on as high as ever

After five days of this course she was no better, save that her bowels were more quiet The skin was dry, temperature 105°, with considerable nervous disturbance, and still semi-conscious As the case was assuming a very serious aspect, I again resorted to the ammonia treatment Dropping all other medicines as in the former cases, I ordered 2 grains every hour until she should sweat The nurse told me the next morning that after giving the fourth dose she began to sweat, and by the time the fifth was to be given, her clothing was so thoroughly saturated that the time was lengthened to four hours Her temperature was normal, pulse soft and regular, though weak, tongue moist for the first time in five days and showing evidence of becoming clean From this time she gained rapidly without one unfavorable symptom, and in one week was up, and soon recovered

Netta B, a frail and delicate girl of 7 years, was attacked with whooping-cough, which ran a severe course for two weeks and then, insidiously, the case took on broncho pneumonia Temperature rose to 104°, breathing hurried, oppression excessive, the lips and face turgid and cyanotic, pulse rapid Gave her a mixture of carbonate of ammon, acetat potass, syr ipecac, and tinct nux vomica as a cardiac and respiratory stimulant, alternating with small doses of qui-After using this treatment four days, the fever not abating and other symptoms becoming worse, I again quit all other drugs and adminimistered 2 grains of salicylate of ammonium every two hours until free perspiration occurred, which was after the sixth dose The fever subsided, respiration became easy and expectoration abundant. The temperature did not return above 101° for several days Although it is a peculiarity of broncho-pneumonia to lull, and give a deceptive promise of amendment, I am convinced that the remedy acted promptly in lessening the fever, for after the second and third invasion of the The next case in which I used the new drug was bronchial tree, with temperature of 104° and 105° also one of remittent fever A boy, 5 years old, had (that after four weeks proved fatal), the salicylate of I put ammonium each time brought the temperature down to 101° or 101 5°

I have given this form of ammonium in other cases, but did not have the opportunity to watch its effects as in the above In the first case reported, I was forced to seek some other remedy, from the unpleas ant effects of quinine. In the second, I had not yet become interested enough in the new drug to give up the old form of medication, while in the third, I once in four hours. Saw the case next day and thought the little girl too dangerously sick to try new found no fever, tongue clean, skin moist, and the remedies. In the fourth I was desirous to test its boy in every respect improved He had no relapse, virtues only after first using the ordinary plan of

treatment

What is there in salicylate of ammonium that arrests high fevers so abruptly? Had the quinine, in the two intermittent fever cases, neutralized all malarial poison and, when the salicylate was given, ushered in the sweating stage? Or, was it the germicidal, antiseptic and antipyretic powers of the salicylate that ever, possible by a few minutes' manipulation and acted so happily? May it not have been the supplying the nitrogenous waste with the ammonia? There that the foot does not readily spring back into its old is a something in its make-up that subdues arterial tension and chemically destroys the microorganisms the surgeon and gradually but persistently unfolded Its effects seem to be as marked in in the blood one case as in another, whether malarial, measles, or whooping-cough complicated with broncho-pneumo-Professor W S Haines once said to his chemistry class that he believed it possible to so perfect the science of chemistry, and so thoroughly understand disease, that we may neutralize and destroy the disturbing element in the system with the proper not by fits and starts, but continuously and persistchemical, timely and scientifically administered The three patients recovered rapidly, while in the one with whooping-cough the fever was greatly reduced three different times

The drug is not stimulating, but rather depressing, and should be carefully watched when given to children in doses of from 2 to 3 grains every one or two hours, and should depression occur, use some diffusible stimulant I have thus far used Mallinckrodt's preparation and given it in pure water, which makes a pleasant medicine that children take readily

MEDICAL PROGRESS.

OPEN INCISION AND IMMEDIATE RECTIFICATION IN CONGENITAL CLUB-FOOT —In an article on this subject read before the New York Academy of Medicine, on Dec 12, Dr Charles N Dixon says

A description of the treatment of club-foot will be facilitated by a division of the deformity into the following three classes I Those that can be easily reduced by manipulation 2 Cases in which there are contractures of fasciæ and tendons 3 Cases in which all the tissues are greatly shortened

It is a common observation that certain cases of club-foot in young children, when handled and manipulated, can easily be placed in a normal position, whereas in other cases in which the deformity is less basis marked, little can be effected without the aid of the It is only in this first class of cases that manipulation and fixation will lead to a permanent result In the great majority of cases it is but a waste of time to attempt to treat the deformity without di-

It has been my practice, previous to any operative interference whatever, to subject the foot to a thorough process of manipulation and in this way discover the amount of resistance that it is necessary to overcome with the knife, and at the same time elimmate all fibrous bands and adhesions that readily yield to the force of the hand much experience in the treatment of talipes must division the distortion can be reduced

have observed, that even in the infant under chloroform the clubbed foot, when pressed by the hand or other force, into the best position it can be made to assume, immediately on removal of the pressure springs back into its abnormal position It is, howpressure so to overcome the resiliency of the tissues position If the foot be grasped by both hands of and twisted into a normal position, at first it gradually yields and becomes improved in position, but soon the shortened structures on the inner side of the foot become tense and refuse to yield, it now becomes a contest between the muscles of the surgeon and the resistance of the deformed tissues the force be steadily continued and even increased, ently, the soft tissues still further yield, the bony surfaces glide on each other, and the foot assumes a position more nearly approaching the normal than would have been thought possible If at any time during this operation there seems to be danger of fracturing the bones, the force used should be intermitted but not entirely let up If the operation is well performed, at the expiration of ten minutes or so the elasticity of the tissues seems to be exhausted and the foot lies limp and flaccid, without that tendency to spring back which it had previously pos-More can be accomplished in ten minutes by manipulation in this way than by ten weeks of plaster dressing according to the old method It must be remembered however, that only the simplest cases can be successfully treated without operation, but this preliminary manipulation should form a part of the treatment of club-foot in all its various de-Most cases will require at least division of the tendo-Achillis and plantar fascia, and the general rigidity of the foot should be the guide in determining the further extent to which the tendons, fascire, and ligaments need division

Whenever the tense structures on the inner side of the foot prevent its unfolding and rectification, owing to their short condition, they should unhesi-In this way tatingly be divided by open incision the time necessary to a cure is shortened, the tendency to relapse is diminished, and the treatment of congenital talipes is placed on a sound anatomical "More can be done As Dr Phelps puts it with a scalpel or tenotone in five minutes than can be accomplished in weeks and often months by all the mechanical appliances known to surgery "

In the second and third classes of cases operative procedures are always necessary As Dr Lewis vision, at least, of the tendo-Achillis and plantar Sayre well says, "contractured tissues cannot be fascia" The distinction between these two classes of cases should be left to the judgment of the surgeon

It should be our aim to produce rectification of the deformity, with as little operative procedure as In many cases the subcutaneous division of the plantar fascia, together with one or more ten-All who have had dons, will be all that is necessary, and after their But if after

subcutaneous division of these structures the foot cannot be replaced, it is better to perform the open operation and divide the tendon of the tibialis pos ticus, the internal lateral ligament, and all other tis sues which offer resistance to the complete redress ment of the foot, if necessary, extending the incision to a linear section of the astragalus and other bones

Operation —The method of operation is as follows Thorough antiseptic precautions being observed, so to the Morris Schede method bloodless by means of an Esmarch bandage the tendo Achillis is divided subcutaneously, and the far back as one will foot thoroughly flexed, so as to overcome the equi Then an imaginary line is drawn from the process of the internal malleolus to the tuberosity of the Taking the middle portion of this scaphoid bone line, an incision is made downward and slightly back ward, across the inner side of the foot, following the direction of the transverse winkle for a distance of an inch and a half The nerve and artery may be protected by being drawn to one side of the wound by means of a blunt hook, which is held in the hand The foot is gradually unfolded, and of an assistant the shortened and contracted structures are divided as they present themselves and offer resistance to replacement, in the following order skin, connective tissue, tendons of the tibialis posticus, flexor longus digitorum, abductor hallucis, flexor hallucis longus, together with the internal lateral ligament A teno tome should then be glided beneath the skin, so as to divide the plantar fascia and the muscular structure of the flevor brevis digitorum These tissues should be cut by a series of nicks rather than by a The wound is allowed to fill prolonged incision with coagulated blood, and dressed with Lister's protective, sublimate gauze, and a plaster bandage the end of which time the wound should be healed

After-freatment --- After the wound is entirely The glass shoe, if it does patient is allowed to walk not become wet, retains its shape for six to twelve Hausmann, of Hamburg, recommends for the after-treatment a shoe which is made as follows The toes are thoroughly padded with cotton-wool, then the foot is covered with a woolen stocking strip of tin one inch in width is applied along the still moist, the plaster cast is cut down the dorsum condyle of the femur to the head of the fibula The shoe thus formed is thoroughly dried in an oven, and covered with leather, so as to make a shoe which can be laced up and removed from time to time -Medical News, Jan 21, 1888

Excision of the Tongue for Epithelioma. BARWELL describes his method and its application in a recent case as follows

The method is this Strictly in and along the middle line an opening is made about one-third of an inch long immediately in front of the hyoid bone, through the raphé of the mylo hyoid The genio hyoid and genio hyoglossus muscles are separated with the handle of the scalpel until the deep surface of the mucous membrane forming the floor of the mouth is reached By means of Liston's needles carried under this membrane to, or even beyond, the last molar teeth, threads are passed on each side as to secure organization of the blood clot according into the buccal cavity, which in their turn draw flex-The foot is rendered ible wire-twist, first into, then out of, the mouth, in First, such wise as to surround the base of the tongue as An écraseur working with this wire severs that part of the organ Then the loop of another ecraseur is passed between the teeth. pressed well down on the first incision, and divides the structures beneath the tongue

In this way, then, I operated on August 6th, on George G, aged 47, who had a large epithelioma on the left side of the tongue, behind its middle, the induration, however, extended very far back and across to the other side of the organ No enlarged glands could be felt The ulcer was extremely sensitive, eating and even swallowing caused pain and trouble to him, while the very foul condition of the mouth took away all desire for food During the operation but very few drops of blood were lost Very soon after recovery from the anæsthetic he wrote on the slate that he was pretty comfortable Aug 8 there had been a copious flow of saliva and other secretions from the supra-hyoid wound patient daily took a large quantity of milk and beef tea, with, he says, more ease than he had done for a long time The wound was frequently syringed and the mouth rinsed with a 1 in 60 solution of carbolic acid, and the breath was hardly at all tainted 24th On the 16th the man could comfortably eat finely The first dressing is allowed to remain four weeks, at minced meat, and had gained flesh since the last re-30th He left the hospital, the tongue nound being firmly cicatrized on the 27th He was able healed, a water glass shoe is applied, with which the to eat very well, and for the last ten days has been able to enunciate with considerable distinctness -Lancet, December 31, 1887

OSTEOTENORRHAPHY FOR RUPTURED PATELLAR TENDON -In the case of a woman, æt 60 years, who ruptured the inferior ligamentum patellæ, CECI performed osteotenorrhaphy by a new method dorsum of the foot, in order to protect the skin when When he saw the patient two days after the accident the shoe is cut off A sole formed of stiff paste- the knee was considerably swollen, there was a hard board is fitted to the foot, and over this another lump under the patella, and on the tuberosity of the A plaster bandage one and a half tibia, where the tendon is attached, was a gap Cominches in width is then applied to the foot, so as to pression was tried for four days without result, and form a shoe extending up to the ankle joint While Ceci then made an oblique incision from the internal opening the joint the capsular ligament along the whole anterior and lateral border of the tibia, including the internal ligament, was torn from the tibia, the inferior patellar ligament was drawn up and fixed by fresh, easily broken-up adhesions washing out with a 2 5 per cent solution of carbolic acid, Ceci bored obliquely through the lower border of the tuberosity of the tibia, by means of his borer for suture of the patella, carried a strong silk thread | put into the cavity On the third day the dressings through, then 3 cm above the site of the rupture, through the patella ligament, and tied it Several fine sutures were carried through the ruptured bor- hæmorrhage was arrested by pressure der of the capsule The skin was then sutured No mon carotid was tied in two places at the level of The patient recovered without fever, with perfect, functional use of the knee - Centralbl f Chirurgie, No 51, 1887

ANYLENE HYDRATE AS A HYPNOTIC -DR AVILIES draws the following conclusions from recent trials of

this drug in Riegel's clinic

I Amylene hydrate is a hypnotic upon whose action one can depend when a sufficient dose is given Comparative trials have shown that amylene hydrate is stronger than paraldehyde, but weaker than chloral

Amylene hydrate acts on people that are accustomed to hypnotics, though it is not necessary to

give larger doses than 4 grams

3 Sleep usually comes on quickly, and without a This sleep is deep or light acstage of excitation cording to the size of the dose, though it is always easy to awaken the sleeper When the person is awakened he is always clear, answers readily, and goes to sleep again if left undisturbed

4 With small doses the sleep lasts from two to three hours, and with large doses from six to eight hours (the larger doses being from 2 to 3 2 grams)

The respiration is not changed by the drug

6 Sphygmographic tracings taken by Riegel on different patients showed that the use of amylene hydrate does not cause any change in the pulse or blood-pressure except those that are normal to normal sleep

7 The patients never have the bad taste and smell after taking amylene hydrate, when they

awake, as they do aftertaking paraldehi de

8 It is not known yet whether a habit is formed But in none of the cases observed was it necessary to increase the dose after the drug had been re

peatedly given

Unpleasant secondary effects were observed in only two cases, and only three patients refused to take the drug It was used in different internal diseases, and had an especially favorable effect in icterus and icteric itching For these affections Eichhorst has recommended chloral, but amylene hydrate is better because it does not cause that weakened condition of the heart that chloral does contraindications to the use of the drug were found In severe disturbance or trouble of the stomach clysters are recommended, and the following formula tation of intestinal parasites may be used 3 grams of amylene hydrate, and 25 grams each of distilled water and gum arabic — Deutsche med Wochenschrift, No 1, 1888

LIGATION OF THE COMMON CAROTID IN A DIPH-THERITIC-SCARLATINOUS ABSCESS CAVITY -SELENkow reports the case of a girl, æt 9 years third day of an attack of scarlet fever she was taken IN COLLAPSE -DR ROSENBUSCH, writing in a Polish with diphtheria, and on the sixth day there was cor- journal, describes some cases of collapse from hæmasiderable swelling of the cervical glands on the right temesis and hæmoptysis in which hypodermic injec-After a week a large fluctuating abscess was tions of chloride of sodium acted most satisfactorily opened by a small incision, and a thin drainage tube | -Lancet, Dec 24, 1887

were stained with blood, which spurted out in a stream when the dressings were removed The comthe cricoid cartilage and cut There was left-side paralysis for about three weeks, which was still partial after six months, and at this time there were great weakness, chordic disturbances, and inability to concentrate the attention The patient answered questions slowly, and stuttered somewhat intellect, though not brilliant before, was weak There was no clear pulsation on the right external maxillary and temporal The left hand was held in extreme flexion and pronation, the fingers balled into a fist, and the thumb drawn into the palm. The patient could change this position only by a strong effort of the will During sleep the hand and fingers were spontaneously relaxed, to return to the abnormal position again when the patient awoke slight blow on the dorsum of the finger caused The muscles on the radial momentary extension side of the forearm were somewhat atrophied left foot was turned inwards slightly, and in walking the right leg was dragged a little -Centralbl fur Chirurgie, Jan 7, 1888

CHLORIDE OF DRUMINE -DR REID, the introducer of this substance to the profession, reports his use of drumine as follows

A short time ago I had occasion to treat a severe Having had a little drumine chlocase of sciatica ride on a filter paper I scraped it off, dissolved it in water, and then filtered it I injected min x of the solution, and in half an hour 3j of solution (strength unknown, as the powder was mixed with filter paper, it was weak, but it paralyzed the sense of taste on There was soon great relief, and ease the tongue) of movement replaced the previous stiff back, so that the patient walked easily down stairs in an hour, when the jarring of ordinary walking formerly gave him much pain No local or after effects appeared, although the powdered drug was six months old ---Australasian Medical Gazette, October, 1887

Antipyrin in Epilepsy —Lemoigne concludes that in most cases of epilepsy antipyrin is inert, and that the cases in which benefit may be expected from it are

I Cases in which epileptic seizures are induced by menstruation

2 Cases in which paroxysms are induced by iiii-

3 Cases in which the attacks are attended by mi-

graine

In these cases antipyrin in doses of grm 2 a day is superior to bromide of potassium - Gazette Med de Paris, Dec 24, 1887

CHRONIC ENDARTERITIS AS A CAUSE OF SUDDEN DEATH

A valuable contribution to legal medicine has just been concluded in the Nordiskt Medicinskt Arkiv, Bd xix, Nr 15, by Dr Algot Key-Åberg, of Stockholm, the title of which is, in English, "Contributions to the Knowledge of the importance of Chronic Endarteritis as a Cause of Sudden Death ' This valuable memoir will be published in the first number of the Vierteljahosschrift für gerichtliche Medicin for 1888, and will be thus more accessible to the profession

In the first part of his paper, which is a sort of introduction, the author notes the differences in the conception of the term "sudden death" from the physiological, pathological, and medico legal aspects, and points out the special importance of the medical jurist recognizing the various anatomical alterations of the human organism that may cause sudden This part of the paper contains an interesting historical review, showing the different opinions that have been held as to the nature and frequency of these anatomical alterations

The author then considers statistically the im portance of chronic endarteritis (Endarteritis chronica deformans, Virchow) as a cause of sudden death, as the term is understood in legal medicine The material upon which this part of the paper is based was furnished by 852 autopsies made at the Medico-legal Institute of Vienna between June 1, 1881, and June 1, 1886, on persons past the age of 14 years that died suddenly The following is a resume of his statistical researches made in the Institute

- I In 745 per cent of all the cases of sudden death, from a medico legal point of view, after the age of 14 years, death was caused by endarteritis chi onica deformans in one of its sequelæ
- 2 In the cases of sudden death mentioned, the sequelæ were, with rare exceptions, one of the following affections paralysis of the heart, rupture of the heart, rupture of an aneurism of the aorta or of one of its branches outside the skull, rupture of the aorta (comprising dissecting aneurism), and intracranial hæmorrhage Of 635 cases there was only one of embolism of the cerebral arteries, in all the others one of the causes just mentioned was the cause of death
- 3 In the cases mentioned, paralysis of the heart was the cause of death in 71 1 per cent, rupture of the heart in 2 4 per cent, rupture of aortic aneurism, etc, in 8 7 per cent, rupture of the aorta in 2 5 per cent, and intracranial hæmorrhage in 15 3 per cent of the cases
- 4 The cases of natural sudden death from a medico legal point of view, after the age of 14 years, gave the following proportions as regards the lethal causes paralysis of the heart 52 9 per cent rupture of the heart 17 per cent, rupture of aneurism of aorta, etc, 64 per cent, rupture of the aorta 19 per cent, and intracranial hæmorrhage 113 per cent
- 5 In the cases under consideration, in which sudden death was caused by chronic endarteritis, the male sex furnished decidedly the larger number This difference was not always so well shown as in the cases in which death was due to paralysis of the heart, or to rupture of an aneurism of the aorta In the first kind of cases the male sex furnished 645 per cent, and in the second kind about 79
- 6 Considered as a cause of paralysis of the heart and of sudden death from rupture of an aneurism of the aorta in the male sex, chronic endarteritis cannot be attributed to senility, since the majority of the fatal cases in these two categories of affections occur between the ages of 40 and 44 years
- 7 As a rule men die from paralysis of the heart due to chronic endarteritis at a less advanced age than women, and it is strongly probable that the same is true of the deaths from aneurism of the aorta seems then that we may draw the conclusion that chronic endarteritis is developed, as a rule, more rapidly, and that it is more harmful, to men than to
- 8 Intracranial hæmorrhages show, to judge from the small number of cases as compared with those of

rupture of the heart and of the aorta, about the same differences in the sexes as just noted

- 9 Social position and calling do not seem, as such, to have any appreciable importance in the etiology of any of the cases of sudden death from chronic endarteritis
- 10 There are more sudden deaths from paralysis of the heart during the first and last three months of the year than during the other six months, the winter season furnishes the greater number of such deaths
- 11 As a rule, deaths from chronic endarteritis are more frequent during winter, next in order of frequency are autumn and spring, and, lastly, summer

There is a possibility, that the author recognizes, that the conclusions drawn from his observations may be influenced by local circumstances, and that in other places than Vienna they might be different

In the concluding portion of his memoir the author considers the presence of chronic endarteritis in the coronary arteries and at their openings into the aorta as a cause of sudden paralysis of the heart is a noteworthy fact that in 33 cases of paralysis of the heart due to chronic endarteritis, which he examinea post-mortem, in 22 there were sufficient reason for regarding the paralysis as the effect of arteriosplerotic changes in the coronary arteries or their mouths He gives the details of 13 autopsies in which death must have been considered as caused by paralysis of the heart exclusively attributable to the arterial Particularly interesting is the sclerosis in question account of the microscopic examinations in these cases, in which the results arrived at are at variance with the opinions generally held especially in regard to fatty degeneration of the heart He makes five special points 1 In 4 cases of 13 fatty degeneration and necrotic softening of the muscular tissue were abso-2 In 2 cases of myomalacia of the lutely wanting heart there was fatty degeneration of the muscular tissue in 1 only, and then only in the immediate vicinity of soft region 3 In 2 cases the isolated trabeculæ of the left ventricle, and in I case one of the papillary muscles of the same part, showed fatty degeneration with coarse granulations 3 cases, in that part of the wall of the right ventricle situated below the trabeculæ, there was finely granular fatty degeneration between the bands of interstitial fat, while at the same time, in 2 cases, smaller regions contiguous to parts of the left ventricle altered in another manner, presented the degeneration mentioned, and in the third case the papillary muscles of the left ventricle showed finely granular fatty 5 In 2 cases only of the 13 did the have asked a thoughtful consideration

muscular tissue of the heart show fatty degeneration over a greater or more general extent of these cases the degeneration had invaded the whole region corresponding to the ramification of the left coronary artery, and in the other the whole heart was invaded by the finely granular form

A QUESTION OF PROPRIETY

Is it proper for a medical reporter having access to the ordinary clinical lectures in a hospital, to attempt to report in full the clinical lectures of a member of the hospital staff, and furnish the same for publication, without submitting a line of his manuscript to the lecturer for his approval? Is it proper for editors or publishers of medical journals to receive and publish what purport to be verbatim reports of clinical lectures without any evidence that such reports have been approved by the lecturer, and without even allowing him an opportunity to read the galley proofs?

We are constrained to ask these questions, partly from personal interest, but more for the benefit of lecturers and editors in general Three times in quick succession the editor of this journal has been surprised, on taking up as many exchange journals from distant cities, to find each opening with a clinical lecture by himself, reported by William Whitford, The first in order of time was on "Typhoid Fever," the second on "Acute Pneumonia-Tuberculosis," and the third on "Broncho-Bronchitis," for the meaning of which we shall have to rely upon the reporter, as there is no such title in our vocabulary We are familiar with broncho-pneumonia and pleuropneumonia, but "broncho-bronchitis" must be one of the new discoveries On looking over these lec tures we found them excellent specimens of the work usually done by stenographers who have not the experience or skill to keep accurately the lecturer's own modes of expression, or the education and mental discipline to enable them to grasp fully and Consequently clearly the ideas conveyed by them the so-called lectures, as they appear in print, present many omissions, many errors, many ideas or points but vaguely or imperfectly expressed, and not a few forms of expression belonging to the reporter, masmuch as they are never used by the lecturer, all of which might have been avoided if the reporter had submitted his manuscript to the lecturer for his correction and approval, or even if the editor had allowed him a glance at the proof sheets our editorial brethren will give the two questions we

ENPIANATION —Early Sunday morning, February 5, a fire occurred in the two upper stories of the building in which The Journal printing office is situated, from which the property belonging to THE windows of the room were broken and the room flooded with water, causing the interruption of our work for a day or two, in consequence of which this number appears with four pages of reading matter less than the full complement. We preferred this much shortage to any delay beyond our uniform day of issue

THE KANSAS STATE MEDICAL SOCIETY will hold its next annual meeting in Representative Hall, Topeka, May 1, 2, 3, 1888 The opening session will commence at 8 o'clock, PM Members and their wives will be passed over the railroads for one full fare going and one-third fare returning A full programme of work has been prepared Further information can be obtained from the Secretary, J E Minney, M D, Topeka, Kansas

THE ILLINOIS STATE MEDICAL SOCIETY WIll hold its next annual meeting in Rock Island, commencing at 10 AM, May 15, 1888 President, Wm O Ensign, Rutland, Secretary, D W Graham, Chicago, Assistant Secretary, Geo L Eyster, Rock Island

LONDON MEDICAL RECORD -The proprietorship of this valuable journal has been changed, and it is to be continued, with its name changed to the "London Medical Recorder "

SOCIETY PROCEEDINGS.

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, January 11, 1888 THE PRESIDENT, J SOLIS COHEN, M D, IN THE CHAIR

DR CHARLES K MILLS read a paper on

THE TREATMENT OF NERVOUS AND MENTAL DIS EASE BY SYSTEMATIZED ACTIVE EXERCISES

(See page 162)

DR HOWARD A KELLY said Some six years ago, while living in Colorado, a friend and myself since died In spite of the condition of his chest he partially theoretical way was able in one month to add a full inch to his chest-

I was practicing at the same time, and capacity succeeded in adding three fourths of an inch to my own This gain was distinctly in chest capacity, and due to increased development of the muscles

I think that Blakie's great merit lies in the ex-Journal received no material damage, although the treme simplicity of the exercises directed, many of which consist in simple rhythmical movements of the Among his most elaborate apparatus for room exercise is a single bar placed between the jambs of the door We should, I think, bear in mind that gymnastic exercises are but the substitute in city life for what people get naturally in the country

A most important point is one to which Dr Mills has referred, that these exercises should be carried out in a medium of fresh air, and not in the super-

heated air of a furnace heated house

A word with reference to respiratory gymnastics When in Rostock with Professor Schatz I had some interesting discussions with him upon the subject of intra-abdominal pressure, and he suggested a series of questions One was, "In which case is the inti aabdominal pressure the greatest, when lifting a bucket of water with one hand, or when lifting two buckets with both hands?" I said that it was greatest when lifting one bucket with one hand, for then we make a column of the abdominal muscles on the opposite side, and necessarily increase both abdominal and intra-thoracic pressure, while in the second case. the strain comes upon the muscles of the back, and pressure is not increased. The keynote to the application of this subject to nervous diseases must be this, that deficient innervation is due to deficiency and irregularity In the circulation, and improvement of the circulation is what is accomplished by gymnastic exercises

THE PRESIDENT said I have long been interested in movement cures, and can recall an interesting case which was under my care in 1860, while a resident at Blockley Hospital A poor wood sawyer had lost the use of his lower extremities as the result of exposure to cold Not many months previously Dr Fayette Taylor, of New York, had explained his method of resistance movements to me, and I determined to try them on the right leg of this man, so once or twice a day I caused the man to try to move his leg against resistance, and moved it myself against his attempts at resistance Some weeks later when I was showing one of the attending physicians the improvement which had been produced in the right leg, the patient suddenly said, "Doctor that is your leg, now look at mine," and throwing off the cover he kicked his left leg vigorously Finding the benefit to the right leg so great, he had quietly practiced on the left leg on his own account, and had done much better with it

DR BENJAMIN LEE said It is now about ten years since the lecturer of to night published a lecture in which the views expressed this evening, and to which we have all listened with so much profit, were somewhat tentatively held It is gratifyfollowed the directions contained in Blakie's book ing that after this lapse of time he can come very carefully My friend was consumptive and has forward and substantiate what he then held in a

The treatment of nervous affections by gymnastic

exercises naturally divides itself into two branches the treatment of functional, and that of organic dis-In regard to functional troubles, I have always felt that the nerves on the whole are the best behaved parts of our economy, that all they want is good feeding When a nerve misbehaves it is because it wants nourishment. Not that the patient may not be putting enough food into his stomach He may be gorging himself, and yet the nerves may not receive a supply of nourishment which is of the proper quality, and adequate to the demands made upon them I believe that in the muscular system we possess the great lever to act upon nutrition, and if we make use of the muscular system intelligently, we can, in the majority of instances, supply to the nerves their needed nourishment, and in that formatory schools way overcome the functional nervous disease

My own experience with the use of active exercises alone in the treatment of such cases has been I have always combined with it massage and duplicated movements—that is to say, those in which the operator either makes a movement which the patient resists, or resists a movement which the The form of exercise in patient attempts to make which the operator makes a movement which the patient resists gives us one of the most powerful means of acting upon nutrition It is what we may term a duplicated excentric movement, or if the term be allowed, an excentric contraction By a concentric contraction of the muscle we understand that which every muscle makes in an ordinary movement, in which the muscle cell contracting in the direction of the axis of the muscle, the latter is in consequence By excentric contraction we understand shortened an effort at contraction on the part of the muscle in which the operator uses a greater force than the patient, and the muscle is really elongated instead of being shortened In this way, the nervous energy of the patient is directed most energetically to the muscle, and yet at the same time, as it is elongated, we are inviting into it an increased supply of blood

The lecturer has referred to the danger of these exercises being carried to excess. This is particularly true where the exercises are carried on in classes. It is essential in carrying out this treatment in nervous cases that each case should be treated singly on its ments.

When we come to the treatment of organic nervous affections, my experience has been that in the early stage of the disease at least, very little should be done in the way of active exercise. We should rely upon massage and passive exercise active exercise should be given in the way of carefully regulated duplicated movements Another important point is with reference to the early use of exercise in all forms of paralysis, and especially in I believe that there are hundreds infantile paralysis of crippled children and crippled adults going about, who, if their cases had been undertaken in the way described by the lecturer, as soon as the slightest trace of muscular power could be observed, would now be able to walk and have the use of their limbs

DR S S COHEN said Dr Mills has referred to the use of exercise in the treatment of criminals

presume that he means more especially the criminal insane It may, therefore, not be irrelevant to quote the views of Dr B W Richardson in reference to the prophylaxis of criminal insanity, or if these be too strong words, the rectification of the inherited moral obliquity which, conjoined with ignorance and misery, leads to law-breaking, by teaching those predisposed to a life of crime, to use their muscular and nervous energies in useful pursuits He would make the prospective forger an engraver, the prospective burglar a blacksmith or a locksmith, and so on arguments advanced by Dr Richardson can be found in a recent number of the Asclepiad, and are worth reading He calls attention to the high importance of this subject by illustrations from the re-He states that children who were unruly and could not be kept in order, have been rendered docile and obedient by having their nervous energies liberated in regular gymnastic exercises at such periods as experience has shown that disorder is most likely to occur

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, October 26, 1887

Vice-President, Dr D S Lamb, in the Chair

Dr Burnett presented a

PIECE OF BONE DISCHARGED FROM THE EXTERNAL EAR,

and said As the question of cerebral abscess following affections of the middle ear comes up for discussion to-night, I have thought it would be interesting to present a specimen and give the history of an interesting case. In November, 1882, Dr Busey requested me to see a young woman with an affection I found her of the middle ear and facial paralysis suffering from inflammation of the ear and facial On examinaparalysis of several month's standing tion I found the auditory canal filled with polypi The polypi were removed in the presence of Drs The facial paralysis soon disap-Busey and Adams The treatment was continued for several months and a number of polypi were removed Dilute alcohol was used to the granulations The treatment was discontinued for three or four months when she returned with the ear full of granulations I did not act so promptly and the symptoms were more In about eighteen months I redifficult to subdue moved a small scale of bone one-half centimetre in She then length by two millimetres in thickness went to office She had scarlatina in childhood In the autumn of 1884, she was attacked more violently than before the attack lasting two or three weeks He scraped the middle ear, the temporal bone was exposed and rough, but there was nothing to remove except the granulations which sprang up rapidly He scraped every week or two but found nothing to remove but the granulations She became worse through the winter until March when symptoms of pyæma I developed Dr Busey agreed with him in the diag-

There was neither pain nor redness over the rotunda mastoid They thought there was pus in the mastoid cells and called on Dr Thompson who drilled but The disease went on for four or could find none five months without any decided improvement times he would shake the bone but found nothing He could not tell the amount of disease in the temporal bone. There were signs of improvement when she determined to try the mind cure She remained under it during the fall and winter of 1885, and seemed to become very much better, but she kept on syringing the ear. In the spring of 1886 her sister removed the piece of bone presented from the external meatus the morbid process apparently ceased It is impossible to tell what the specimen is, but he thinks it a part of the semicircular canals Her intelligence is Smith's case up to the average

CEREBELLAR ABSCESS DUE TO DISEASE OF THE EAR

DR Jos H BRYAN, in opening the discussion said. I think in opening the discussion on an important subject like the one we have for this evening, it will be of greater advantage to the Society to figures will be found nearer correct middle ear disease, rather than to relate my own ably the most frequent, and the cerebellar the least so limited experience

middle ear ways result disastrously, if left to take care of themselves, in either one or more of the three direct sequalæ meningitis, phlebitis and thrombosis, and abscess of the brain prominently before us, why is it we meet with so any attention and allowed to become chronic, inter-

That secondary diseases of the brain arise from otitis has been known for a long time, according to Schwartze, since the time of Avicenna and Morgagni It is, however, due to the researches of such men as Toynbee, Sedillot, Virchow, Frolich and Schwartze, of our own time, to establish the different ways by which inflammation can extend, and the different forms of disease that can be developed thereby

The extension may take place from an acute outs, but it is generally due to the chronic form of inflam-At times it is very difficult to discover the path of the inflammation, especially when there is no caries present, or congenital opening between the tympanum and cramal cavity. In this connection the relation of veins and sinuses to the petrous is

Once having reached the labyrinth it can easily extend along the course of the facial and auditory nerves through the porus auditorious internus Probably the most common path is by direct extersion to the membranes, producing a septic leptomeningitis, and thence to the cortex of the brain The veins which drain the posterior part of the temporo-sphenoidal lobe empty into the superior petrosal sinus, and the septic matter which is absorbed by the sinus can be taken up by these veins and by a so-called retrograde phlebitis carried to the interior of the tempero sphenoidal lobe, thus giving rise to those cases in which the abscess is separated from The discharge stopped and the petrous bone by healthy brain tissue

Cerebellar abscesses generally result by means of caries and localized meningitis, as occurred in Dr

According to Schwartze, about one-half of all abscesses occurring in the brain are due to inflammation This is a higher per cent than of the middle ear that given by Lebert and Myers-which I believe is about one-third-but I think as the pathology of the disease is being better understood that Schwartze's The abscess give a synopsis of the advances in the pathology and may be found in either the spheno-temporal lobe, or treatment of abscesses of the brain resulting from is sub dural in the cerebellum. The sub-dural is prob-

Toynbee believed that the localization of the abs-I am glad that this Society has had an opportunity cess depended upon the part of the bone affected, of having its attention directed to the evil effects of but this does not always follow, as has already been this too often neglected disease—suppuration of the stated, the seat of the abscess may be some distance The chronic inflammations nearly al- from the bone, and separated from it by healthy brain tissue

From numerous observations made in the postmortem room, Mr Barker, of London, 1s led to locate With these facts standing as the abscess either over the roof of the tympanum, close to the squamo-petrosal suture, or on the posmany of these neglected cases? In the beginning it terior surface of the petrous bone, and in some cases requires very little attention to check a mild case of it extends from one to the other of these spots otitis media, indeed the inflammation occasionally Hence, he concludes that the abscess is usually subsides like magic Notwithstanding this we occa- found in the middle, or posterior part of the temporocionally meet with cases which have never received sphenoidal lobe, and that nine-tenths of them will be found to lie within a circle with a radius of threefering with the patient's comfort and endangering fourths of an inch, whose center lies one inch and one quarter above and at the same distance behind the center of the auditory meatus

When the cerebellum is the seat of the abscess it is usually found in the anterior and outer part of the lobe, just back of the posterior surface of the petrous

Although experimental physiology is rapidly locating the cerebral centers, I think they are not so firmly established that we can rely upon their disturbance in all cases to the exclusion of the general subjective symptoms, but they are of very great value when taken in conjunction with the general signs Owing to the inconstancy of the subjective symptoms we frequently find it very difficult to make a diagnosis, and much more so to locate the abscess It is not an uncommon occurrence for the abscess to revery important, as is also the fold of the dura mater main latent for a long while, to break out only upon which extend sdown into the squamo petrosal suture the receipt of a blow on the head, a fall, or after of the tegmen tympani The inflammation may ev- some undue mental strain During the latent period tend to the labyrinth through the fenestra ovalis and there may have been no symptoms pointing to the

brain lesion. What are we to rely upon to make our doned for the flap operation. Great stress is laid diagnosis? It is only by carefully considering all the upon the fact that the flap must be so outlined as to symptoms, both general and special, that we can hope preserve in its attachment either the superficial, temto come to any definite conclusion not of much value as a symptom of localization, for 1t has been customary to reflect the periosteum as a it frequently happens that the abscess is in an entirely different part of the brain than that indicated by the in that the membrane is easily torn and lacerated Diplopia and optic neuritis, when present, are of value—for the latter symptom is frequently wanting The temperature, which runs up to 102° and 103°, accompanied by rigors, to fall later on to subnormal, is a valuable sign. The pulse is generally Mr Barker calls special attention to this subnormal temperature, which was much lower in the had been possible to locate the abscess in Dr Smith's The above-mentioned sympevening in his cases toms, together with the frequent nausea and vomiting, and what special signs there may be present, especially following in the wake of a chronic suppuration of the middle ear, we can in most cases come to a When the abscess is associated definite conclusion with meningitis, or phlebitis and thrombosis it is impossible to make a diagnosis

The prognosis of abscess of the brain is far more favorable than it was formerly, and we have something more to do now than simply to make our diagnosis and wait for the autopsy to confirm it Through the labors of M Lucas-Championiere and Mr Victor mations of the ear Horseley, the skull has been mapped out and such definite directions given that we can enter the cramal cavity and open an abscess of the brain with almost as much safety as one occurring in other portions of

our attention to its cause

It is an unfair reflection to cast upon otology to say that the advances made in the treatment of abscess of the brain has been greater than those for the treatment of its cause—chronic suppuration of the We are to-day able to cure a great many of those chronic cases which a few years ago When the inflammation were pronounced hopeless does not subside under mild treatment, then radical cure or Schwartze's operation should be done, and the parts can thus be kept perfectly drained so that the possibility of sepsis is greatly diminished the disease has advanced and the abscess formed, meningitis? then the skull must be opened, at the same time

keeping up the drainage from the ear

The great questions to be decided in operating for abscess of the brain are when and where to apply the trephine trephine as soon as we feel convinced that there is an abscess, and not to wait until the vital forces become exhausted and the patient is in a comatose Knowing that nine-tenths of the abscesses are to be found in what is called the "dan- nasal douche which caused inflammation of the midgerous area," we would naturally apply our trephine dle ear and meningitis, and the patient died somewhere in the circle described by Mr Barker, if should impress parents with the gravity of diseases we decide the case to be a cerebral or subdural ab- of the ear and the importance of early treatment to draw a line from the post-occipital protuberance accompaniments of teething, and that they will get to the tip of the mastoid process and apply the trephine at the middle of this line By this means there acid to excel all other remedies is no danger of entering the lateral sinus Horsley the inflammation does not extend too far insists that the old crucial incision should be aban-

Headache is poral or occipital arteries. As regards the reflection, separate layer, but this has an obvious disadvantage This is obviated by reflecting it in continuity with the rest of the flap

The incision for the flap in cerebellar operations should be a curved one, commencing at the postoccipital protuberance running downwards and terminating at the apex of the mastoid process. If it case, I think it would have been a favorable one for It would be interesting to know the damoperation age to the petrous bone It seems almost impossible that so much destruction of the interior of the bone could take place with no other symptoms resulting

than those given in the record of the case

This is a very interesting ques-Dr Burnftt tion, and it only needs somebody to start the subject, so he would offer a few thoughts The main question is respecting the treatment, and, with due deference to general surgery, there has not been much advance made in treating the complications of inflam-They should be treated early The general practitioner orders the usual treatment for otitis and the discharge ceases. The ear is washed out, but the disease is going on all the time The mucous membrane is thickened and inflamed Before treating the abscess let us direct There is loss of nutrition and disease of the bone Patients must be treated The healing power is lost early and watched for months afterwards a return upon the slightest exposure, showing that The physician does not the disease was not cured His case has taught him a always see these cases lesson in bone surgery, so that if there is necrosis in The operation for that locality he will let it alone mastoid abscess is more frequently performed than At the last meeting of the Otological So formerly ciety there was an unusual number of specimens presented The journals are giving numerous deaths If If you empty the cerebral abscess do you cure the

good or bad fortune to have to make a post mortem examination in a case of his own, he has had occasion to see quite a number of them during his hospital practice. He has seen many cases of purulent do with brain and ear surgery. Trephining in itself otitis media cured by timely treatment When neglected cases come into our hands and we find the bone denuded, we might at first try Wilde's incision, which sometimes is sufficient, but, as a rule, the ing, but the results were unfavorable original seat of the trouble being located in the mastoid cells, the opening of the mastoid bone either by chisel or trepan is indicated. The longer we hesitate the more chance there is for the development of a cerebral or cerebellar abscess Cases of this kind usually follow in the wake of measles, scarlatina or post-mortem examinations of children dying of a complication of scarlet fever with diphtheria, that taking out the walls of the auditory canal Trephinthe tympanic cavity is filled with a kind of pseudomembrane or exudation This diphtheritic affection of the middle ear is not always diagnosticated and the patients, in some cases, gradually recover apparently without there being any attention, perhaps, to the very slight symptoms indicating trouble in the would statistics encourage such an operation may get entirely well, but if the scarlatina or measles ful operations are being performed within the skull residuum of the exudation in the middle ear is not resorbed readily, and forms a nucleus of inflammation which results in perforation of the drum and consequent purulent discharge If this discharge is fetid it is significant of affection of the bone quently, when the bone is laid bare, it can be seen or felt quite easily after the ear has been thoroughly washed out-of course with a disinfecting fluid But if the caries is located in the mastoid cells—and this is frequently the case—we have to rely on other data for our diagnosis Fetor, constant headaches, pain on tapping the mastoid bone, fever and a number of other symptoms will soon enable us to make our diagnosis certain By performing Schwartze's operation on the processus mastoidous, by which he has with the parts affected, and allow the pus accumulated in those cells to escape instead of letting it work its way towards the brain find any accumulation of pus, but little harm is done by the operation If the bone is affected we should always operate and give the patient a chance

DR BURNETT was misunderstood about the operation which he meant to be applied to abscess of the Many men are opposed to operative interference and perforation of bone, and others cure without operation He believes in cutting into the mastoid, and in his case he went into a healthy

There is but little danger in tre-Dr Reyburn phining, and he has never seen a death from the operation, they die, but not from the trephining He saw two of the cases operated on by Victor Hors-When he reached the dura mater there was nothing unusual to be seen, so he cut into the brain and found the tumor imbedded in its substance The rarity operation was performed for epilepsy, and he saw DR SWITH

the man walking about the ward, and learned that there had not been a return of the attacks

DR J FORD THOMPSON has had considerable to is simple enough, the questions are where to trephine, the diagnosis and the prognosis Years ago the practice was very common as a means of searchnot to trephine, but to locate the abscess time ago Dr Busey and himself saw a case with Dr Prentiss A man 40 years old had earache which was followed by symptoms of pyæmia and the post-mortem revealed an abscess of the petrous bone which had ruptured into the lateral sinus He has had occasion to observe, in In Dr Burnett's case he opened the mastoid cells, but did not find pus No surgeon would think of ing will open the abscess and prevent its extension in the opposite direction Dr Smith only saw his case just before death, and it would have required nice diagnosticating to have made out the condition An operation would not have benefited him, nor If they have a good constitution they will open an abscess anywhere he finds it Wonderis followed by a long convalescence and general de- Dr Weir recently removed a tumor from the cerebility, then the ear trouble is sure to show itself The bellum, but the patient died Durante diagnosticated a tumor in the cerebrum over the orbital plate opened the side of the skull, elevated the frontal lobe and removed a tumor the size of an egg, and the If there is a guide to the seat, patient recovered as pain, paralysis, aphasia and facial paralysis, we can apply the trephine near enough When the disease is in the interior of the brain substance we have no such guides The practice of cranial surgery is attended with frightful mortality He recently saw a case which had received a blow months before, he soon lost interest in his business, and very soon coma He diagnosticated abscess of the brain, came on and the post-mortem confirmed it This was a case for operation if the diagnosis had been made earlier

DR GODDING had some instructive statements of saved many lives, we establish a free communication autopsies of the insane which were wide of their In children it is for the general practitioner to diagnosticate these affections they only come to If we should not him with the sequelæ that is, inflammation of the brain following scarlatina They are not cases of abscess of the brain going to a fatal termination Dr Blackburn has informed him that he has not seen a case of abscess of the brain We have seen tumors which he could not recall In one case the tympanum was perforated when the man was comatose, but pus was not found, he died either from abscess or meningitis, which could not be verified, as a post-mortem was not allowed A case of chronic mania of sixty years' duration, in which there were delusions and fantasies, but no paralysis nor sexual disordered function, was found dead A soft tumor was found in the cerebellum He had gone about without any of the usual evidences of such pathological conditions In 1,300 deaths the absence of abscess of the brain would indicate its comparative

To differentiate intercranial abscess

from disease of the internal ear is usually very diffi- last child she had miscarried at the third month pus and detritus passing one way and the inflammation the other patient died comatose In the next there was a dis- painful After recovery the pain in the left side charge from the middle ear and extensive cellulitis subsided One year ago the growth began to inof the neck He opened the mastoid, but the patient died brain from ear disease In another case the physician had told the family that the patient had pneuat the first doctor The autopsy revealed an abscess of the brain and also pneumonia Dr Prentiss reported a case in this Society The discharge from the ear had ceased Dr Thompson aspirated the liver, but did not find pus

in regard to the case reported by Dr Prentiss There was no dispute in regard to the existence of almost impossible to get at the tumor, and certainly an abscess, but its location was not definitely deter-The man had had one or two very severe rigors daily, attended with a fever varying from 105° to 106°, and a constant pain with acute exacerbations in the region of the lower lobe of the right lung There was a history of ear trouble, but at the time there was no symptom which directed attention to There was neither a discharge from the ear, nor any swelling or tenderness about it, nor any brain The constant and violent pains at the symptoms base of the right lung, together with marked circumscribed dulness extending above the liver surface, suggested a possible abscess of the liver pressing For this Dr upwards into the thoracic cavity Thompson aspirated, but failed to find any pus in The autopsy revealed an abscess in the brain, and a condition of the lower lobe of the right lung which was believed to have been caused by numerous emboli It is not impossible that a similar condition of the lung was present in the lung of the patient referred to by Dr Smith, and that the physician who made a diagnosis of pneumonia may not have been far away from the fact

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, Fridav, November 18, 1887 THE PRESIDENT, HENRY T BYFORD, M D, IN THE CHAIR

THE PRESIDENT presented a

FIBRO-SARCOMA OF THE UTERUS AND BROAD LIG-AMENT

This specimen of the fibro-sarcoma of the uterus is interesting, as having been obtained by one of the most difficult hysterectomies on record I have three hours after the operation of exhaustion the following notes of the case

married twenty-two years, having borne four child- The absence of menorrhagia in the history of the ren, the oldest twenty years of age, the youngest case corresponds with what is more often noticed in twelve years old Four times since the birth of her sarcoma

There may be a discharge from the ear, the Her present illness began six years ago, when she discovered an enlargement in the left inguinal re He has had three cases die from ear gion There was no pain connected with it, but the In one with disease of the middle ear the last miscarriage, three years ago, was extremely crease in size, and has grown very rapidly since In the last there was an abscess of the There was dull, heavy pain through the pelvis Two months previous to this time an exploratory incision was made and a diagnosis given of fibroma of The man died and the family were incensed the uterus, with numerous pelvic adhesions surgeon did not think its removal practicable August 4th I removed the tumor The operation was begun at 3 15 P M and completed at 7 15 P M The tumor, including the uterus, was about the size of a man's head I found the whole anterior sur-DR Busey desired to correct some misstatements face of the omentum firmly adherent to the abdominal wall above, and the tumor beneath, making it quite impossible then to made an ordinary explora tory incision It required about three quarters of an hour to get the omentum, whose veins were as large as goose quills, ligated so that I could free it from the surface of the tumor After enlarging the incision, I found a little space on the right where there were no adhesions All over the left side the small intestines were adherent, lying flat on the surface, while above and on both sides the colon, throughout its whole length, lay as if plastered upon the tumor Large blood-vessels could be seen run ning from the bowel on to the tumor If I could have lifted the tumor sufficiently to put an elastic ligature about the uterus I might have quickly enucleated it, but I could not stir it from its bed was a sarcoma that did not easily admit of enucleation, and bled profusely from the slightest wound The patient was anemic, had already lost some blood, and had been under ether for some time But I had to go on, for I did not dare to close the incision with the already disintegrated surfaces free in the abdominal cavity So by ligating dozens of places, cutting between some ligatures and enucleating under others, I finally got the tumor so that I could raise it a very little Over two hours were thus consumed before I succeeded in fieeing it above and tying the ovarian vessels of the left side I then rapidly enucleated far enough down to apply an elastic ligature, using all of my hemostatic forceps in stopping bleeding points. But the uterus had grown into the broad ligament and was firmly attached to the pelvis, so it could not be enucleated out of its vascular surroundings, but had to be ligatured at and against the pelvic brim on the left The pedicle, as you see, was about the size of a man's thigh, and is traversed on one side by the en larged uterine cavity It was treated by Hegar's extra-peritoneal method The patient died fortygreater extent and vascularity of the adhesions, as Mrs E W, American, aged 40, widow, had been compared with fibroma, were well illustrated here

DR ETHERIDGE -Will you tell us how you freed | quested to meet him the colon from the tumor, and whether the bladder

nas implicated?

THE PRESIDENT - The bladder was not impli-In freeing the colon I took stitches through the capsule of the tumor and ligated separately the large vessels on the other side and cut between In some cases I used hemostatic forceps on the tumor side, in others I enucleated

THREE PELVIC PRESENTATIONS, WITH DEEP LACERA-TION OF THE PERINEUM

The three cases of breech delivery here reported occurred in close sequence in my private practice Being unusually severe labors, and having certain points in common, they impressed me as being worthy of report Taken collectively, they suggest discussion as to the management of labors with this presentation

Case I - Mrs W, American, æt 26, primipara, was taken with slight labor pains 4 A M, May 7th, 1887 At 2 A M, May 8th, Dr Colton was called trol of the rectum to-day and found the breech presenting, S L A os was but partially dilated, and the pains extremely irritating, he administered opium and chloral Rest. with gradual dilation of the os was thus obtained for the next twenty-four hours, when I first saw the os still not sufficiently dilated, the breech not being 24, 1887, I was called to attend her in her second I advised non-interference and a contin- labor uance of the opium per rectum

At the end of twenty-four hours I was again sent for Water had been escaping for hours, the breech rested on the perineum, the patient was exhausted by seventy hours' labor, and the fetal heart could not be heard The doctor had made long and faithful efforts to assist the delivery, but the body was apparently impacted in the pelvis and would not With great difficulty I succeeded in bringing down a foot, and at length delivered a

lifeless twelve-pound boy

The after-coming head caught in the superior strait and its extraction with forceps caused a laceration of the perineum to the right side of, and beyond, the anal sphincter The soft parts were so deemed unadvisable

The perineum was partially repaired by granulation during a tedious convalescence of five weeks

Secondary operation will be required

Case 2 -Mrs M, a stout young Bohemian, æt May 13th, 1887 Dr Michelet in charge first stage of labor was tedious and extremly painful The membranes ruptured at the end of twenty silver sutures hours For three succeeding hours pains were severe and expulsive, when the patient became exhausted and labor ceased Dr Nelson was called in and advised stimulants, quinine and opium patient slept several hours, awoke refreshed, and the pains returned with strength and regularity

We found the breech resting on the perineum, the body firmly impacted in the pelvis, and the child dead Persistent efforts at extraction had been made, leaving the vulva bruised and swollen and the permeum rigid The patient having been put under ether at the request of the others, I engaged a blunt hook in the anterior groin of the fetus and gradually succeeded in extracting The forceps were then applied to the the body DR I SULDAN KNON read the following report of after-coming head. Its delivery caused a laceration of the perineum through the sphincter, and about one inch up the recto vaginal septum The weight of the child was ten pounds

Under the most disadvantageous circumstances Dr Nelson successfully closed the rent, using three silver sutures in the septum and four in the perineum

Antiseptic post-partum treatment was adopted, but the patient had septic fever On the eighth day feces escaped per vaginam Examination revealed no union, and the stitches were removed The patient was four weeks in bed For two months she was confined to the house She has but little con-

Case 3 —Mrs F, a robust American woman, æt 36, was confined four years ago, in New York, with After several hours of distressing her first child labor a dead and mutilated child was instrumentally extracted I could not learn whether craniotomy Finding the membranes unruptured, and the was practised or not On the morning of June I found the vertex presenting high up L O The first stage of labor lasted thirty-six hours, when, the os being fully dilated, I ruptured the Hard expulsive pains succeeded for membranes three hours, when, finding the head did not engage, I attempted the high application of the forceps

The blades were introduced and locked without difficulty, but each attempt at traction caused them to slip backwards over the crown of the child Owing to the great obliquity of the head, this always occurred in spite of extreme depression of the handles and downward traction Anesthesia was then produced, the hand introduced, and podalic version

easily accomplished

The after coming head became impacted in superior strait, requiring the forceps Fifteen or twenty swollen and contused that immediate stitching was minutes passed before it could be disengaged and delivered By depressing the handles of the forceps between pains I succeeded in getting some air to the child, and thus finally delivered it alive

of child, twelve pounds

My best efforts could not save the permeum, 22, fell in labor with her first child the morning of which was torn through the anus and one inch up The the recto vaginal septum After the delivery of the placenta, I repaired the laceration with two deep The upper stitch was inserted on a level with the lower vaginal commissure and passed entirely around the recto-vaginal rent The second stitch closed the perineum above the sphincter ani The rectal sphincter not having been repaired, the condition of the patient was similar to that after operation for anal fistula The stitches were re-Thirty-nine hours from the commencement of the moved on eighth day, finding the perineum healed labor Dr Nelson was again called in and I was re- The patient was up and about in two weeks, appar-

October 13th, the rectal tear of judgment ently as well as ever not fully healed, but sphincter under full control My impression is that no further operation will be comfort would have followed the closing of the

required

In reviewing these cases I was impressed with the danger to the fetus in delay of delivery after the membranes have ruptured Until then, breech presentations should not be interfered with, for the dilation of the os is slowly accomplished, and the membranes should be kept intact as long as possi-This long first stage, however, is apt to exhaust the patient and make her irritable We thus get spasmodic rigidity of the os tincæ and perineum

After the rupture of the membranes, and the protrusion of the breech into the vaginal canal, the rigid perineum is apt to cause the flexible body and folded limbs to pack in the pelvis, and delivery is If this retardation continues, tonic uterine contractions are induced, and the child dies asphysiated, or uterine inertion comes on and the fetus slowly dies from compression In the cases reported, the large size of the children, and the easy delivery of the after-coming heads, show that impaction was not due to disproportion between

the pelvis and the fetus

These successive complications I believe are present in some degree in all breech presentations The novelty of the situation, with its pain and anxious forebodings, tends to make such parturients nervous and irrritable Under ordinary conditions, breech presentations should be severely let alone until the breech has cleared the The bag of waters can scarcely be left too long unbroken, the folded body best prepares the way for the after coming head, and, therefore, the hausted in attempting to dilate the perineum and extremities should not be brought down Tractions lead to extension of the chin and the passing of the arms above the head, and, therefore, ordinarily are unwise and vicious

In cases, however, like the first two reported, there must be a departure from the ordinary methods, to avoid the ill results that followed

In a prolonged first stage, the resulting irritability of nerve and muscle can largely be avoided by a free use of opium guarded by belladonna is thus secured, strength conserved, the os tincæ becomes relaxed, and the permeum distendible

After the rupture of the membranes, the descent of the breech should be encouraged by pressure upon the fundus uteri during each pain At the same time, two fingers in the vagina depressing the permeum would prevent impaction and increase the energy of the uterine contractions Should impaction threaten, anasthesia should be induced, the feet brought down and tractions made, always, however, following the descending fetus with com-This outline of treatpression of the fundus uteri ment is, of course, to be modified by the idiosyncracies of the patient or peculiarities of the case

Each of the three patients reported was deeply Each laceration was treated differently

were so edematous and bruised as to forbid expecta- the head, or whatever the presenting part is, reaches Case I was not operated upon I believe this to have been an error the perineum. You have the advantage of the reflex tion of union

The edema soon subsided, there was no sloughing, and partial repair at least with much The mere apposition of the parts without wound union is a great advantage to the patient, as illustrated in Case 2

The latter was far less distressed during the first week of her lying-in, though her laceration was much

more grave and no union resulted

In Cases 2 and 3, both lacerations passed through the sphincter ani, and about an inch up the rectovaginal septum In Case 2, the whole wound was carefully closed with seven silver sutures union resulted Septic fever was, however, present In Case 3, but two sutures were used, one closing the vaginal rent and the other the perineum. The deep anal fissure was left untouched Good union followed

I believe these opposite results had their origin in the management of the torn sphincter ani deep lacerations this muscle is a born disunionist, and chases under the restraint of a stitch It should The end be excluded in the closing operation sought is to restore the integrity of the perineum Even the rent in the recto-vaginal septum, unless

extensive, is of less importance

Perhaps it would be more DR D T NELSON appropriate for me to say something later in the discussion, but as I was cognizant of the first part of the history of the case, it may be interesting to state the condition of the patient before Dr Knox saw her and kindly assisted, for I assure you we wanted not only his brains but his muscles The attending physician and myself had become completely excervix and make ready for some one to deliver believe I never saw a more rigid perineum, the cervix had dilated fairly well, but slowly and tediously, assisted I believe, by opiates—chloral had been given by the attending physician before I saw her In theory and practice I have no doubt of the importance of aiding dilatation of the perineum when it does not dilate satisfactorily This was one of those cases, rarely found, in which it was exceedingly difficult, almost impossible, to dilate Considerable had been accomplished before Dr Knox saw the patient, and yet I am sure he would be ready to testify that the perineum was not well dilated, and more, that it It was ruptured before it was was not dilatable As to the wedging of the fetus into the dilated pelvis or into the lower strait, it was to me an interesting fact, and I think I have seen it several times before It ordinarily means the death of the fetus Thus wedged in, when dead, the fetus is, so to speak, a ball of putty which can be crowded by the forces above into a mass against the resisting medium, whatever it may be Pains had been increased by the manipulations in dilating the perineum, and I think that is an important advantage in many cases of difficult labor, that by attempting to dilate the perineum the pains will be strengthened, just as they The soft parts are ordinarily in a normal condition of things when

muscular contraction which makes the pains very But we had become exhausted much more powerful patient, so we got very little advantage in that way It seems to me the proper place for improvement in treatment of such a case is during pregnancy or be fore pregnancy even, and the question is whether or not we could do anything to make the muscular structure better in quality. It seemed to me one of those cases in which there was, to a large extent, ab sence of the development of muscular structures in the vagina and perineum which ordinarily follows pregnancy We are all aware that pregnancy makes a great change in the vagina, vulva, uterus and ovaries, and it seemed to me that change had not taken place as it should There had not been the development of the muscular structures that would facilitate the delivery She was much in the condition, when I first saw her, of a virgin She was quite fleshy, and I think it is the experience of all of us that these are the patients whose perineums and other structures rupture, they do not dilate as well, perhaps from absence of muscular tissue, perhaps from the presence of fat As to the restoration of the permeum, I remember well that we discussed the question whether it would be wise to attempt the immediate operation of the restoration of the perineum and other ruptured parts after delivery, my own thought, and I think it was the unanimous belief of those present, was that the woman would be no worse off if the immediate operation was performed. and probably would run less risk of sepsis, though we all doubted the satisfactory union of the parts heartily agree with Dr Knov that, as a general rule, at is not wise for us to try to close the perineum and be thoughtless about the recto vaginal septum and the sphincter ani I should decidedly prefer, if I was to operate after another physician, to have the septum closed, and to have the opportunity of closing the sphincter and perineum I think the first operation should be the closure of the septum I think it will be found quite difficult to close the recto-vaginal septum, after the penneum and sphincter have been I fully believe that the danger of sepsis and other serious complications are lessened by the immediate operation, even though the parts are so lacerated that we can hardly expect a satisfactory union, and I would do the primary operation unless the patient was so exhausted by the previous delivery as to forbid it

DR CHAS WARRINGTON EARLE Such difficult breech cases as our attention has been called to this evening are not frequent in my practice Indeed, when I have seen pelvic presentations terminated before I could reach the case, safely to both mother and child, it has sometimes occurred to me that we exaggerated the dangers of these cases, and I have thought that the ordinary breech case gets along better without some doctors than with them

advisers, I believe the most judicious treatment was pursued, but I cannot see why episiotomy was not in attempts at dilatation before Dr Knox saw the performed. This is an operation which, in my judgment, should not be done frequently or unadvisedly, What advantages have we gained by the experience? but it occurs to me that here it would have been iustifiable

Dr Nelson compares the condition of the child in

the cavity of the pelvis to a mass of putty

With such a condition of things as this—the child dead and the lower parts rigid—why waste time trying to deliver with forceps or anything else, why not perforate at once, reduce the size, and then deliver?

In regard to lacerations, I am an advocate of closing them all I have never performed the immediate operation on the cervix, but I have witnessed it, and, if performed by a skilful operator, I think it justifi-Certainly, it is our duty to do the immediate operation if the perineum is ruptured I once saw Carl Braun's assistant do a craniotomy, in the course of which the cervix, a portion of the vagina, and the permeum were all torn After the usual antiseptic precautions to the cavity of the uterus, he introduced retractors, and successively closed the rent in the cervix, then in the vagina, and then the perineum. using in all about sixty sutures

I can easily see how in a small room, and with imperfect facilities, it would be impossible to do such an operation, yet the indications are, to thoroughly and antiseptically and immediately close these lacer-

Dr. D T Nelson I would like to say a few words in reference to some of the points raised which Dr Knox did not know As to the use of hot vaginal douches, the hot sitz-bath was not used, it was practically impossible, on account of the absence of conveniences A hot-water vaginal douche was directed and repeatedly used during the first stage of labor A word further with regard to the septic conditions I believe the woman had septic fever, but I believe that antiseptic precautions were fairly used, not as they might be in a hospital, or as they would be in our best private practice Vaginal douches of an antiseptic type were repeatedly used during the first stage of labor, and after delivery iodoform was constantly thrown into the vagina and over the vulva As to closure of the permeum by primary operation, and putting in too many stitches, I have had some experience in that direction, and fully believe that putting in a large number of stitches, and closing the parts perfectly, is a desirable thing to do, and I have repeatedly had it succeed most admir-I never had as bad a result as this one, and the reason is partly explained by the fact that we were working at a decided disadvantage not think it safe to put the patient on the table, where we could have had an opportunity to perform the operation satisfactorily More than half the stitches were put in by feeling, and not by the eye, and you can judge that they would not be well put in, and I think accurate coaption could not be secured there is no doubt but that the temptation to extract pectation was not that there would be complete quickly sometimes produces the complications we union, but that there would be less sepsis than other-The cases presented by Dr Knox wise, and I think the woman would have had far less were indeed complicated, and, with his most able chance of life if the operation had not been attempted

think any gentleman would have found it a difficult I used no intra-uterine douche, but used an antiseptic task to turn that babe and deliver it the parts before the instruments are put on, it seems to Dr Earle, the physicians were not trying to save easy, and in every other case of breech presentation the perineum, as the lacerations were not at all ex-I ever saw it was exceedingly easy to deliver the pa- pected tient, but this was so extremely difficult I was very the after coming head in breech presentations, and glad to have Dr Knox present to assist, as well by always expect to deliver the head without laceration his fingers as his valuable head If I should ever of the perineum meet another such case, I would be glad to have some gentleman of the Society present, and if he can deliver with his fingers, they will be stronger than any that were present on this occasion, I feel sure there are no fingers in this Society that could have delivered that breech

I would like to take exception THE PRESIDENT to one of the main conclusions of the paper, that it is not well to try to do too much in closing the peri-In those cases in which I have put in the most stitches, the union has been the most complete I recently put in twelve stitches and got complete shall or Hunyadi water I like them to have a stool union, in a laceration extending into, but not through, once in twenty-four hours without the use of an the sphincter ani sphincter ani, I obtained complete union by using I preserved a piece of the perineal fifteen stitches centre, which was hanging out like the end of a finger, by stitching it back with buried juniper catgut The reasons for failure are that the operation is poorly done, or imperfectly cared for afterwards the operator uses carbolized catgut, he will be sure be closed, if possible, and that every care should be to have occasional failures I use buried sutures of juniper catgut in the recto-vaginal septum, instead tion of rectal sutures, and then stitch the vaginal edges, exactly as they belong, with the same material lowest external stitch should be taken low down and through the ends of the torn sphincter, as recom-Either this or the next one mended by Emmet should pass deep enough into the perineal body and neum, unrepaired at the time, and left for a secondary near enough to the rectal mucous membrane to sustain the rectal pressure or traction as far as possible If these stitches be of silk-worm gut or silver, they will not give way, when properly and aseptically I think the mistake is sometimes made of cutting off too many irregularities, instead of fitting them together After the parts are united, we should, if the rectum has been lacerated, bind up the bowels for several days, and at first use plain vaginal douches, not carbolized ones, from three to five times in Beginning with the third and twenty four hours fourth day, carbolized douches should be employed If we take all this care, the same as for the secondary operation, we will, unless the parts have been too badly bruised, have the same success

In regard to the infection of DR J S KNOX these patients, Dr Cotton told me his patient had no septic fever or rise of temperature, and he thought convalescence was delayed on account of the lacera-Dr Michelet's patient had septic tion of the parts The stitches were removed on the eighth day, and union was found not to have taken place my own case, the woman made a prompt recovery I kept her in bed two weeks, because I had stitched pains but the dilation of the os, I think, is a signs of sepsis, she had a normal lying-in I intro- dred, but by dilating the perineum when it is rigid I

As to turning and delivering the child by its feet, I | duced my hand into the uterus and turned the child As to dilating vaginal douche, two or three times a day In reply I have repeatedly applied the forceps to It has been my experience that when a delivery of the after-coming head is attempted instrumentally, it comes suddenly and unexpectedly, you make strong traction, and the head flies upon the permeum and out in the world in a moment, and I think the lacerations of the perineum occurred in this sudden popping out, so to speak, of the after-coming Dr Byford speaks of keeping the bowels bound up after operations of the perineum with greatest success in keeping the bowels open, my inflexible rule is, after stitching the permeum, to administer to my patients, from the start, Friedrich-In another extending through the enema, I also like my patients to pass urine naturally, and then, as soon as the patient has unnated, to douche out the vagina and the wound it is not judicious to keep the bowels constipated In regard to Dr Nelson's criticism of my conclusion about too much being attempted, I spoke only of If this one case I believe that all lacerations should taken to perform an immediate and complete opera-When, however, the conditions are such that one cannot make a complete operation, I should much prefer to close the permeum, leaving the sphincter ani muscle unclosed, to even leave the septum not stitched, rather than the perineum, because I believe that the results of a laceration of the peri-There seems to be a operation, are quite serious readjustment of all the organs of the pelvis, the position of the bladder, rectum, and uterus are not the same as before, and the longer the secondary operation is delayed the greater are the displacements In this operation, I said, too much was attempted, because an appropriate and satisfactory operation could not be done under the circumstances

All the surroundings were such that all operations were done with a great deal of difficulty, in fact, Dr Nelson made half his stitches by touch, and not In my own case I was alone with no asby sight sistant but an ignorant Irish nurse and with a hysterical patient In the case operated upon by Dr Nelson, I think, if he had used less skill, he would Speaking from my have had a good perineum personal experience, I think that manual dilation of the os in labor is injurious, I believe most thoroughly in the septic inoculation of the uterus by attempts to dilate the os in labor, even before the When the os has become membranes are ruptured rigid, I occasionally introduce two fingers and try to retain what dilation has been accomplished by vicious practice in ninety-nine cases out of a hunhave saved a rupture, in breech as well as vertex however, lasting only fifteen weeks presentations If impaction of the fetus and laceration is accomplished largely by rigid perineums, I think it is proper for the physician to do this operation, and I know that it does bring on more regular

DR Larle asked if these women were subjected to a long hot sitz bath as a means of assisting dila-

tion?

DR KNON—They were not There are many things that have suggested themselves to me in connection with these cases I believe that if hot vaginal douches, hot sitz-baths, and hot applications over the abdomen had been used, they would have been more satisfactory

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK !

(FROM OUR OWN CORPESPONDENT)

Prophylaxis of Diphtheria—Induction of Premature Labor in Amain osis and Amblyopia from Albuminuria of Pregnancy

At the second January meeting of the Academy of Medicine, Dr A Caille read a suggestive paper relating to the prophylaxis of diphtheria. He said that it was a fact that members of certain families, and especially children, had an attack of diphtheria every spring or autumn, and it had occurred to him that in all probability in such cases the microbes of the disease remained permanently in the system, continuing in a dormant condition until some hyperæmia of the faucial or nasal mucous membrane afforded an opportunity for the diphtheria to break out afresh. The disease was thus propagated by a process of autoinfection

In order to make a practical test of the correctness of this hypothesis he selected eight individuals, of different ages, all of whom had had diphtheria at least twice—some of them a considerable number of times—prior to October 1, 1885 All belonged to families whom he had long known and who had continued to occupy the same residences or apartments The first thing that he did was to cause all carious teeth to be filled or extracted He then directed the mouth to be rinsed, the throat to be gargled, and the nose to be cleansed three times a day with either a 3 per cent solution of potassium permanganate, a weak solution of liquor sodæ chlorinatæ, or a saturated solution of boric acid, the different solutions to be alternated with each other from time to time In very young children the antiseptic solutions are dropped into the nostrils with a pipette tice was maintained throughout the year with the exception of the summer months, during which none of the subjects had ever had diphtheria

As a result, apparently, of these precautions, not one of the individuals referred to has had an attack of diphtheria up to the present time, although some of them in the meanwhile have been exposed to the disease by other members of the family having it, While this result, Dr Caille said, did not, of course, afford absolute proof of the truth of the view advanced by him or of the prophylactic power of such a plan of procedure as that described, it did go to show that if the nasal and oral cavities are kept clean by antiseptic washes, diphtheria was less liable to occur than if no such precautions were taken

He then went on to say that hitherto in diphtheria said that if the nasal douche was avoided and warm far less attention had been paid to the matter of pre-fluids were used in the form of spray or by dropping

vention than to that of treatment One reason why was because of our ignorance in regard to the nature and significance of so called diphtheria, and since we could not in many instances distinguish between a contagious and a non-contagious sore-throat, the problem presented was a very unsatisfactory one to Still, as there was no specific treatment deal with for diphtheria, prophylaxis, in the present state of our knowledge, was of more value to the public at Prophylactic measures might large than treatment be divided into those relating to general sanitary conditions and those confined within the family was an unfortunate fact that in a large city the great majority of the inhabitants were unable to live in perfectly healthy dwellings, and hence the great importance of individual prophylaxis was obvious

Dr Caille concluded with some additional remarks on individual prophylaxis He stated that enlarged tonsils increased the liability to diphtheria, and recommended that these should always be removed with the knife or, better, the galvano-cautery Canous teeth should be extracted or filled, and he thought that provision should be made by which the poor could have dental cavities stopped with cement or amalgum free of charge or at a merely nominal price He advised that parents should inspect their children's throats every morning before sending them to school, and that all children should be taught how to gargle at an early age Children with sore throats should not be allowed to go to school Kissing children on the lips should be forbidden, and parents should be urged to keep the upper air-passages of their children in as healthy a condition as possible

In the discussion following the reading of the paper Dr George T Harrison said he had had such painful experience in the treatment of diphtheria that he was especially glad to hear something in regard to the prophylaxis of the disease, and he believed that the adoption of such precautionary measures as had now been suggested would be a step in the right direction. He was also glad, he said, to hear Dr Caille emphasize the danger connected with so-called follicular amygdalitis, to which Dr Jacobi had directed attention, as this was a matter in regard to which the profession as well as the laity, needed to be on their guard

Dr Fruitnight said it was a common experience to find that the first case of diphtheria in a family had advanced to a very dangerous degree before the medical attendant was called in, and, consequently, was very likely to prove fatal. It was also noticeable that afterwards in such families the parents themselves often instituted a system of prophylactic measures, making it a daily practice to examine the children's throats, etc.

throats, etc

Dr S Bamch said he should think that the daily washing out of the nose by the insufflation of cold liquids was a very dangerous practice, on account of the hability to excite serious ear trouble

Dr Caille explained that he did not recommend the employment of cold liquids, and Dr T R Pooley said that if the nasal douche was avoided and warm fluids were used in the form of spray or by dropping into the nostrils, he did not think there was much risk of crusing disease of the middle ear. The safest and best method of washing out the nose was by

means of the post-nasal syringe

Dr Seibert called attention, by way of supplement to Dr Caille's paper, to the importance of keeping children's stomachs in good condition, in order that the mouth and tongue might be clean In his experience a furred tongue was always a hotbed for the development of diphtheritic trouble, and he thought that the candy shops in the vicinity of the public schools were responsible for a good deal of the diphtheria now so prevalent

The President, Dr Jacobi, said that if he understood the reader of the paper rightly, he held that when a patient had once had diphtheria the germs of the disease are likely to remain secreted in the mucous membrane and lymphatic glands, and he quite agreed with Dr Caille in this opinion of the worst cases of diphtheria were those in which there was immense glandular swelling with cedema Such cases were very likely to prove fatal, but if the patients recovered the improvement dated from the time when these symptoms began to diminish was convinced, therefore, that diphtheritic germs were hable to remain in the lymphatics

If, as has been remarked, the mouth and nose were in a healthy condition, diphtheria was always less likely to occur, while, if an epidemic of the disease appeared in a neighborhood, the children living there who had a catarrh were especially hable to be attacked Diphtheria was like erysipelas in this respect When there was an epidemic of the latter disease in any locality the slightest scratch was likely to induce an attack of it, while those who were free from any

sore or abrasion of the surface escaped

There was another way in which diphtheria recurred, and in connection with this there was a point of great practical value in its prevention to which Dr Jacobi said he desired to call attention often been noticed that cases in which it was thought the attack was about over had a relapse, and in some instances there would be three or four attacks in quick succession The reason for this was simply because the room, the bed, the curtains and the carpets had become infected, and he had therefore made it a rule, whenever this was practicable, to change the room of the patient every two or three days, even if the room to which the removal was made was not as desirable as the one first occupied In some cases he had found it necessary to have the patient taken out of the house altogether

In answer to a question by Dr Holt, as to whether there were any sufficient data to indicate that children with enlarged tonsils were more subject to diphtheria than others, Dr Caille said that his own experience went to show that such children were more hable than others to be attacked, but he had found that as a rule the disease in these cases was of

a comparatively mild form

Dr Jacobi said that the reason why the tonsils were cause they stood so much in the way of the air-current,

Again, whenever the tonsils were enlarged on them there was a liability of mucus accumulating behind Enlarged tonsils were usually combined with a subacute or chronic nasal catarrh or pharyngitis, and the sooner, therefore, the tonsils were reduced, and the pharyngitis removed, the better would be the prospect of the child's escaping diphtheria

Dr Joseph W Winters said that when diphtheria appeared in a family, in addition to enforcing strict isolation and attending carefully to disinfection and the general sanitary condition of the premises, he inspected the throat of every member of the household daily, and if there were any children, ordered them to take full doses of tincture of chloride of iron (say 20 drops or more, three times a day), and tonic At the same time he directed that doses of quinine they should be kept in the open air as much as possible, should sleep in rooms free from pipes connecting with sewers, and be given simple diet Their digestive organs should be maintained in good condition, and to this end he usually prescribed small doses of mercury as a purgative two or three times When adopting these precautions he rarely a week saw cases of diphtheria occurring in the same family

On the same evening Dr T R Pooley read a paper on "The Induction of Premature Labor in Amaurosis and Amblyopia from Albuminuria of Pregnancy," in which the following conclusions were

arrived at

In all cases of pregnancy, not only should examinations of the urine be systematically made, but the eyes should be examined with the ophthalmoscope, since, in a large proportion of cases where eye-troubles exist, the patients make no complaint of disorders of vision Frequently such troubles can be detected with the ophthalmoscope long before any disease of the kidney is shown in the urine

2 In uræmic amaurosis without changes in the eye visible to the ophthalmoscope, even should the usual accompanying symptoms, such as dizziness, nausea and threatened convulsions, be absent, their supervention is soon to be anticipated, and the immediate induction of premature labor is indicated, without waiting until the life, as well as the sight of

the patient is in danger

3 In neuro retinitis the induction of premature labor is not only justifiable, but urgently demanded In some instances it is called for even in the earlier months of pregnancy

4 It is required in certain cases of eye-trouble

recurring in successive pregnancies

5 A woman having once suffered in this way during pregnancy, the relationship of cause and effect should be fully explained both to herself and her husband

ASSOCIATION ITEMS.

LIST OF OFFICERS -- When the list of Officers of so frequently the primary causes of diphtheria was be- the Association was published the address of Dr F C Hotz, Chairman of the Section on Ophthamology, so that deposits were extremely liable to take place Otology and Laryngology, was incorrectly given, owing to a somewhat recent change It should have been 103 State St, Chicago, Ill

The chairmen of several of the Sections have already reported lists of excellent papers promised for vantageously be increased in number, in order to the coming meeting

BOOK REVIEWS.

THE RECTUM AND ANUS Their Diseases and Treat-By Charles B Ball, M Ch, F R C S I, Surgeon to Sir Patrick Dun's Hospital, etc. With 54 Illustrations and four Colored Plates 8vo, pp viii 410 Philadelphia Lea Brothers & Co, Chicago A C McClurg & Co

This is a systematic and complete treatise of over 400 pages, well illustrated, and brought down to the present in point of all important improvements Considered as a whole the work is much more fully elaborated than either Allingham's, Curling's, or Kelsey's, although apparently not a large treatise, being printed after the custom of the Lea Brothers, in compact form, on thin paper Little attention is given to the injection treatment of hemorrhoids, which the author speaks very slightingly of same may be said of various other methods of the American "rectal specialists" Without directly intending it, probably, the author very neatly pricks the pretentions of those that claim originality for the discovery of rectal "pockets" by giving quite a complete summary of the pathology and treatment as practiced by many surgeons in ulcerations of these pouches were anatomically very well known, but that they have been split up and otherwise operated upon many times by surgeons for various reasons chapters of this work are commendable for the thoroughness and clearness of their discussion, and none more so than that upon fissure, which gives the best contribution we have as yet seen to the pathology and causation of this singular affection

THE THROAT AND ITS DISEASES, Including Associated Affections of the Nose and Ear, with 120 Illustrations in Color, and 200 Engravings Designed and Executed by the Author, Lenox Browne, F R C S E, etc Second edition, Rewritten and Enlarged 8vo, pp 614 adelphia Lea Brothers & Co, Chicago A C McClurg & Co

The author of the volume before us will be remembered by many American readers who attended the last International Congress for the able paper that he presented and discussions that he took part in, as well as for his genial, kindly manner first edition of this work has been well known, but has been completely rewritten by the author for this, the second edition In reading the book one cannot but be impressed with the clearness of the exnot but be impressed with the clearness of the explanations and the practical character of the advice The beauty, fulness and correctness of the illustrations enhance the value of the work very greatly The colored illustrations, which are beautifully ex-

ecuted, are much better than those of any similar text-books with which we are acquainted chapters on diseases of the nose and ear might admake the work still more complete doubtedly prove one of the most popular works upon the subject, both among practitioners and students

MISCELLANEOUS.

THE WILLIAM F JENKS MEMORIAL PRIZE—The First Triennial Prize, of Two Hundred and Fifty Dollars, under the Deed of Trust of Mrs William F Jenks, will be awarded to the author of the best essay on "The Diagnosis and Treat

ment of Extra-uterine Pregnancy"

The conditions annexed by the founder of this prize are, that the "prize or award must always be for some subject connected with Obstetries, or the Diseases of Women, or the Diseases of Children," and that "the Trustees under this deed for the time being, can in their discretion publish the successful essay, or any paper written upon any subject for which they may offer a re ward, provided the income in their hands may in their judgment be sufficient for that purpose, and the essay or paper be consid ered by them worthy of publication If published, the distribution of said essay shall be entirely under the control of said Trustees In case they do not publish the said essay or paper, it shall be the property of the College of Physicians of Phila delphia"

The prize is open for competition to the whole world, but the

essay must be the production of a single person

The essay, which must be written in the English language, or if in foreign language, accompanied by an English translation, should be sent to the College of Physicians of Philadelphia, Pennsylvania, U S A, addressed to Ellwood Wilson, M D, Chairman of the William F Jenks Prize Committee, before January 1, 1889

Each essay must be distinguished by a motto, and accompa Not only does it appear that these nied by a sealed envelope bearing the same motto and contain ing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay

The Committee will return the unsuccessful essays if reclaimed by their respective writers, or their agents, within one year The Committee reserves the right to make no award if no

essay submitted is considered worthy of the prize

ORIGINAL ARTICLES.

A CASE OF EPILEPSY CURED (APPARENTLY) BY THE CORRECTION OF AN ERROR OF REFRACTION

Read before the Chicago Medical Society, January 16, 1888 BY J ELLIOTT COLBURN, M.D.

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY IN CHICAGO FOLICLINIC OPHTHALMIC SURGEON TO COOK COUNTY HOSPITAL ASSISTANT SURGEON ILLINOIS STATE CHARITABLE EYE AND EAR INFIRMARY ETC

attention, first came under my observation in June,

160 lbs, well proportioned, features regular, except that eyes are deeply set and appear small, occupation student

He consulted me for mental confusion and inability to read or study without flushing of face and pulsating of superficial arteries, with sensation of poundof vertigo which would disappear when eyes were At times, following prolonged effort, the confusion of ideas was painful and was accompanied by visions which he recognized as such, at least a part of the time He had at this time some slight field soon increased his trouble disturbance of digestion and constipation, due apparin early boyhood, but not since, had had frequent me for advice seminal emissions, more marked during the past two found him at my office in a truly pitiable plight case remained about the same About this time, for lusions some conduct not in accord with the rules of the institution, he was brought before the Faculty President, finding that he had consulted me, came to find out whether the gentleman was really ill, or whether there was good reason for his strange ac- and advice tions and low standing in the school From him I notes of his case learned that the patient was constantly manifesting strange mental phenomena, by them attributed to times he was extremely dull and morose, and again almost brilliant and exemplary

I then inquired more carefully into the case from

sermons, while it was with difficulty that he was able to grasp the matter of a printed page. He was advised to leave school for some occupation less sedentary and requiring less mental work. This he did At the end of the summer vacation he returned apparently perfectly well

About this time I left that field of work and lost track of my patient From a student in the institution at that time I learned that for some weeks following his reentrance he did good school work, but resumed his old habits and, after a stormy time with the Faculty, left the school After some difficulty, The following case, to which I wish to call your he was admitted to the ministry, for which he had About two years subsequent to my been preparing first acquaintance with him, during a sermon, he was Mr T, æt 24 years, 5 ft 9 in in height, weight attacked with a marked epileptic seizure, and from that time on he was subject to attacks more or less severe, occurring in the frequency of from one a day to one in two or three weeks

Restraint was considered advisable, and he was confined in an asylum at intervals for about two years During one of his more prolonged intervals of iming in back of head and neck, with marked sensations munity from fits he escaped from the asylum and went to a neighboring State, where he endeavored to resume his work, but the return of the malady again unfitted him for ministerial labor and he resorted to The study necessary for success in this canvassing

About this time he recalled my opinion and progently to sedentary life He admitted masturbation nosis of his case, and finding my address called upon He came to me in August, 1886 years and always following hard study I gave him had been a number of hours on the cars and had such treatment as his case seemed to demand, with had numerous seizures more or less severe, he was the result of benefiting his digestion, otherwise the hungry, bewildered and incoherent, with marked de-I hastened to put him in better condition, and on the following day elicited some of the facts given above

His trouble continued in spite of sedatives, and I referred him to Dr C D Wescott for examination Dr Wescott gives me the following

"Mr T first called upon me October 23, 1886 I pronounced him an epileptic as he entered my office, viciousness and low mental and moral character At from his appearance alone, the congested countenance and excessively mobile pupil He described very well seizures of petit mal occurring every two or three weeks with or without unconsciousness, frehimself and others, and diagnosed a condition bor-dering on petit mal, with impulses I also found that lucinations His judgment was evidently impaired, he was unusually bright as a critic of orations and and he presented every appearance of one suffering

TRADE OF SEVENTEDAY CASES—CONTINUED					
Observer	Age of Patient	Tumor Recognized	Symptoms	Fluctuation	Diagnosis Refore the Operation
13 —Freund Loe cit	30 years Nullipara				Double fist sized myoma of the uterus and a tu mor in the left broad ligament.
14—Freund Loc cit 15—Bantock The Brit 18 Gyn Jour, A., August, 1887	fer 10 years	14 days after the removal of a sub peritoneal myoma as large as a man's fist, a plum sized tumor of the left broad ligament was detected. Tumor recognized nine months before operation, soon after the birth of the last child			Solid tumor of the left broad ligament which became as large as a child's fist, still separat ed from the uterus by a distinct furrow Believed to be ovarian
16 — Fenger Unpub lished	29 years Multipara	About one year	Crused little inconvenience, but aroused the suspicion of pregnancy	None	Solid tumor of the left broad ligament. Sepa rated from the ovary and uterus by a recognizable space, filling the pelvis and extending half way to the umbilicus, some what movable Uterus and ovary separately movable
17—Holmes (Opera tor, Streeter) In this article	1	Tumorrecognized eleven months before operat'n, when it wis movable from the uterus		Pseudo fluctur- tions	Tumor of the right ovary

The sutures were removed from the abdominal wound on the fourth day, and the second and last dressing applied to the abdomen. There was not a particle of suppuration at any time, nor any pain in the line of the abdominal cut, or in the region of the operation. There was just a show of blood on the vaginal tampon where it lay against the os uteri. The patient was somewhat troubled with borborygmus during the first week, and at the end of a month had an attack of gastro-enteritis. She has now regained her former health and strength, and has menstruated regularly and normally

The tumor has all the appearance of a uterine fibroid It is almost perfectly spherical and smooth The cut sur-It is about the size of a man's fist face is smooth and white, with a few cavernous sinuses, filled originally with a clear serous fluid A piece of the fibrous capsule is still attached to one The drawings which I present side of the tumor were made from stained sections, with a one-tenth inch immersion objective, and an inch eye-piece The nuclei resemble very much those of unstriped muscle There is very little, if any, pure fibrous tissue to be found in the body of the tumor Near the blood-vessels, the nuclei are ovoid or spherical, and These are, no doubt, the round cells very large noticed by Kleinwachter (49) in small uterine fi-They seem to be well nourished cells, undergoing rapid mitosis, or indirect cell division These large round cells are easily distinguished from transverse sections of the long nuclei by their size and arrangement

This tumor, then, is leiomyoma, that is, a myoma that originated from a matrix of smooth muscle tissue

Such a matrix is found in the uterus, in the uterine ligaments, in the base of the ovary, in the walls of the bladder, and in the abdominal wall

(a) A consideration of the history of the case shows conclusively that this tumor did not originate as a sub-peritoneal fibroid of the uterus. When first observed, it was quite a distance from the uterus, and freely movable from it in the pelvis. The pelvis was thoroughly examined under an anæsthetic four months previous to the appearance of the tumor, and nothing found

It does not seem possible that a fibroid of the uterus could be so completely displaced either by puerperal contraction, or by the traumatism it suffered at the operation in February

There remain to be considered the possibilities of an ovarian or a ligamental origin for our tumor

(b) We have four methods of demonstrating the presence of smooth muscle-fibres in the broad ligament, the embryological, the anatomical, the physiological, and the pathological The uterine ligaments contain plain muscle-fibres, which are prolongations of the superficial embryonal layer of the uterus These fibres extend through the ring into the mons veneris, and out on the abdominal wall to the linea alba, and up over the posterior wall of the bladder

Anatomically, these smooth muscular fibres have been found and described by Rouget (14), Klebs (16), Henle (17), and Luschka (19) They are also mentioned in Quain's Anatomy

None	Free	Not found	Transverse incision thro the broad ligament and enucleation of the ses sile immovable tumor	Leiomyoma of the right broad ligament weight, re ounces	Recovery without complication In perfect condition Nov 28 1887	ıl .

They have also been assigned an important rôle in initiating labor (18) In examining the wall of cysts of the broad ligament, Spiegelberg (20) and Lawson Tait (21) have seen layers of unstriped muscular fibres three or four millimetres long investigators have sometimes found and sometimes missed these bundles in the walls of parovarian cysts There is, then, no doubt that a suitable matrix for the development of leiomyomas is found in the broad

Graetzer (26), investigating the origin of the tumors of the abdominal wall, has opened up all the possibilities of the origin of fibroid neoplasms in every part of the body According to the theory of Cohnheim, there must be a matrix derived from the mesoblastic layer of the embryo Thus the fibroids of the œsophagus, stomach, intestinal canal and prostate from the plain muscular fibres of these organs, and those of the abdominal wall from fibres going out from the uterus through the ligaments in the direction of their embryonal attachment

Twelve well diagnosticated connective-tissue tumors of the round ligament have been collected by Sanger (2) These represent almost every possible theoretical position in which such a neoplasm could be found, namely in the round ligament, in the pelvis, in the canal and outside the canal, in the walls pedicle of the abdomen, or in the labia majora

broad ligament The tumor was as large as a bean, and so smooth and spherical like ours

far removed from the uterus and from the ovary that no relation of origin to them could be considered Such tumors have been thought by many investigators to arise from a displaced fragment of the ovary, or an accessory ovary

If any doubt remained of the possibility of the primary origin of fibroid, or better, of desmoid tumors in the broad ligament, the careful consideration of Cohnheim's post-mortem examination, reported by Freund (28), would remove it He found on the posterior wall of the uterus and of the bladder, and between the leaves of the broad ligament, even to the outer end of it, numerous isolated myomata of all sizes, from a cherry to an apple

Sanger (1 and 2) has collected eleven cases of primary desmoid tumors of the broad ligament which the skin arise from musculi erectores pili, those of reached a considerable size. There are several observations by other authors which swell the number of observed cases to nineteen or twenty

> Then it is both possible and probable that our tumor arose originally from the broad ligament in which it was found It is still necessary to show that it did not arise from the ovary

> (c) There are at least three reasons for thinking that it did not arise from the ovary, namely the form of the tumor, the microscopical elements of the tumor, and its manner of attachment, or want of

The fibroids of the ovary are simply hypertrophies Small fibroids have been occasionally found in the of the connective tissue of the ovary, and therefore Virchow (9) has made such an ob-their contour is irregular and nodulated, and not

Fibroids of the ovary are composed almost entirely of fibrous tissues, and unstriped muscle-fibre is rarely and sparingly found, while our tumor is composed almost, if not entirely, of plain muscle-fibres

Fibroids of the ovary have been shown by Leopold (28) to be connected with the ligament by a long, simple pedicle, which does not include the tube One tumor lay deep and sessile in the pelvis

It is not significant that a diagnosis of an ovarian tumor was made before the operation, as this has been repeatedly done by other operators in the case of solid tumors and cysts of the ligaments

Neither does it matter that the right ovary was not recognized, as it is frequently melted down on the surface of large cysts, and becomes almost unrecognizable through pressure atrophy

I conclude after all these considerations that this is a true primary leiomyoma of the broad ligament

A table is appended to this article giving a synopsis of the eleven cases collected by Sanger (1 and 2) to which I have added six other cases Three of these are from Freund (28), one is from Bantock, and one is from an unpublished case of Fenger, and the other is the case I have just described

In only six cases was the true position of the tumor recognized before the operation, namely, Schmid's, Miculicz's, Freund's three cases, and Fenger's

Cystic, cavernous, and sarcomatous myomas, as well as simple myomas, are represented

The average age of the patients is about 32 years,

the extreme being 19 and 42

It is probable that these tumors are not so rare as this limited number would indicate, but that in the advanced stage of growth in which they come to operation, the ovary becomes drawn out and lost on the wall of the tumor, which then seems to have arisen from the lost ovary An earlier examination would perhaps have revealed their true position

THE TREATMENT OF NERVOUS AND MENTAL DIS-EASE BY SYSTEMATIZED ACTIVE EXERCISE

BY CHARLES K MILLS, MD,

OF PHILADELPHIA, PA

[(Concluded from page 167)

Systematized active exercises serve a good purpose in some of the various disorders designated as asthma One case of this kind, a young lady, despondent, weak, dyspeptic, hysterical, with feeble heart, and subject to attacks of asthmatic breathing, improved with great strides in a few weeks under general active exercises She began treatment with half pound dumb-bells, and at first could only stand five minutes' The exercises were increased, until half an hour was reached, and dumb bells weighing four pounds were used

In the treatment of chorea, or rather choreas, sys tematized active exercises are valuable Special forms of gymnastics have been employed for this affection to some extent, particularly in France and Napoleon Laisné, a French professor of Germany gymnastics, and evidently an earnest and enthusiastic worker in his chosen field, under the directions of Dr Blache and other physicians of Paris, has used gymnastics largely both for chorea and other con-In 1865 he published a book in vulsive disorders Both Schreiber and which his methods are set forth Dujardin-Beaumetz refer to his labors and successes His method in mild cases, as described by Schreiber, is to place the child before him, steadying it between his knees, and then take its hands in his, and perform rhythmic movements with each arm, keeping time by counting, or, better still, singing, out loudly-"one," "two," "three," etc The child, at the same time, is also urged to try and keep time with the movements, and not to make them irregularly

"Care must be taken in the beginning to prevent, as much as possible, the coincidence of involuntary When the arms movements with the rhythmic ones have been exercised, similar movements are under-From time to time, a pause for taken with the legs rest is made, during which the limb must be held firmly enough to prevent the occurrence of involun-

tary motions upon an inclined ladder, the feet being held by an result of eccentric functioning by nerve centres, or assistant, then grasping a rung above its head, it of irregularities in the conveyance of impulses through holds on in that position as long as it is able is to be repeated several times, and to be followed impulses to be conveyed in a normal manner to by a short rest legs are rubbed and gently kneaded "

Lengthy details of treatment will be found in for months

Schreiber's Manual

Two cases of minor chorea improved under medicinal treatment up to a certain point, and then would advance no further General exercises with light dumb bells were ordered, and in both cases the pro-

gress to complete recovery was rapid

In the treatment of habit chorea, these exercises This, whether in children or have a peculiar value adults, is an annoying and distressing disorder, and By habit chorea is meant commonly intractable an abnormal movement or series of movements, frequent intervals Mitchell2 records two interesting cases, and recommends for treatment careful and good diet, light gymnastics, no school, gentle aperients, and full doses of arsenic, particularly the hy podermic injection of arsenic in the form of Fowler's I refer to this treatment, as he includes solution light gymnastics among the measures recommended

number of cases of habit chorea years ago I reported the case of a girl, fifteen years old, who had peculiar movements of her right ear, after a time associated with twitchings of her nostrils and upper lip, and the limbs of the right side Another patient, under excitement, made a move ment of extension and semi-rotation with one arm, sometimes accompanying it with twitching of the facial muscles Facial grimaces constitute, as is well known, one of the most common forms of habit I have now under my charge a case of habit chorea which is being treated successfully by systematized active exercises The patient, a young lady eighteen years old, began to be troubled with spasmodic movements nine years ago These lasted at first from one to two years, then disappeared for a year to return again, and have since gone and come For the last two years, however, she has been troubled almost continuously with the movements, and has tried various modes of treatment, chiefly medicinal, but without any decided benefit The chorea consists of a sudden jerking of the head downward and to one side, which may be performed once or several times in succession Either with or without this twitch or jerk, she frequently also has a snapping movement of both eyes The chorea was not started by imitation, but it is much influenced by any cause of nervous excitement, as fright

Systematized gymnastics, either general or local, constitute a rational treatment for cases of this kind, because by means of such exercises not only is the general nutrition of the patient improved, but the nerve centres are given tone and strength, and good habits of movement are made to substitute bad

The child is then laid on its back Such eccentric and abnormal movements are the This nerve channels By again and again causing normal Afterward, the shoulders, back, and muscles, in time the choreic habit will be overcome Such treatment, however, needs to be persisted in

The advantage of any treatment which involves specific direction and the adroit calling out of the volition of a patient must be evident to everyone who has had experience with hysteria in its manifold In hysterical paralysis much can be done by laying out a careful plan of treatment by exercises, and gradually leading up to their full performance In referring later to ataxias and palsies, functional and organic, methods to this end will be considered For the improvement of nutrition, and of what may be termed the general nervous and mental tone of voluntary or partially involuntary, and repeated at hysterical patients, systematized active exercises fill an important place Properly used and controlled, they may also prove most beneficial for cases of general nervousness, and also for neurasthema Whatever view may be taken of the much mooted question of neurasthenia, without doubt both respiratory and muscular power, either primary or secondary, are often deficient, and the nerve centres Among my nervous patients I have had a goodly themselves can be strengthened and improved by ex-Nearly thirteen ercising these two powers Care should be taken not to force individuals suffering in this way to excessive effort at first

> Great are the advantages which result from the solourn by sea or mountain, from the cure of camp and ship, but the improvement of health obtained by such holiday treatment is often soon lost in whole or in part by the individual going back too completely to old habits of living and working A resort to systematized active exercises for a few minutes daily will do much toward keeping the good that has been obtained

> "A man," says Maclaren, "cannot, in a week or two, eat sufficient food to supply the demands of the appetite for a whole year, neither can he take sufficient exercise to keep his body in health throughout the four seasons in a summer's ramble These mountain excursions or sea side sojourns must be in addition to, and involving no curtailment of, the daily walk to and from business, the daily ride to and from somewhere, or the daily employment with or at something, a something which will in its doing, quicken the pulse and augment the breathing and, if possible, bring the perspiration to the forehead "

> For those forms of nervous palpitation which are dependent upon a neurasthenic condition associated or not with digestive disorder, systematized active exercises are of great value. The exercise should at first be light, but should be carefully and somewhat rapidly increased Besides the indoor exercises, after the method of Blaikie, or with the pulley-weight apparatus, the patient should use deep breathing while walking out of doors A case reported by Dr Theodore Clemens, of Frankfort-on-the-Main, is interesting in this connection The patient was a man forty-

² Lecture on Diseases of the Nervous System Especially in Women by S Weir Mitchell M D Philadelphia Medical Times March 28 1875

Medical and Surgical Reporter, October 22 1887

six years old, who applied for treatment on account ments, with intervals between of a minute or more of distress and irregularity of the heart. Clemens decided to make him do the thing he most dreaded, weak, a finger beneath the ankle aids it, but no atviz, climb up several flights of stairs was most happy The patient's pulse, which had in- orders are to be obeyed more quickly. It is easy termitted at every tenth or twelfth beat, wavered to sketch out for one's self what such a system only twice, and but slightly, in a hundred beats after should be in its details. After it has gone far he had mounted three flights of stairs twice. He enough the patient is seated in bed with some supnow decided to make similar efforts regularly every port to her spine, and is trained to move the head day, and in three months he was a well man

method of using gymnastic treatment will be found most wanting, should be cautiously encouraged bosis, tumor, abscess, or depressed fracture, less frequently of meningitis or cerebritis, of atrophy or arrested development, and still more rarely of ure Sometimes in cases of sudden lesion, as hem orrhage or embolism, the assault upon the nervous system is so violent, or the destruction is so great that death results quickly, or the pa-tient is reduced to a state of utter helplessness, for which, practically, nothing can be done many cases, however, soon after the attack, or even the same truths apply at a later period, the amount of palsy is dispropor-Many cases of monoplegia and hemi plegia illustrates this truth Little by little some of these patients regain muscular power to such an extent as almost to induce the belief that they will get entirely well, indeed, in some cases of hemorrhage, tumor, traumatism, syphilitic meningitis, and uremia, complete or almost complete recovery does occur treatment of such patients

and after the shock of the attack, and the acute in- venience electricity, and possibly massage, allowing the pa-|cord tient to use the affected limb as he sees fit More system, may play a useful part Every effort conthe paralyzed limb with the volitional centres Such patients often need to be incited to effort

Two methods of systematized active exercises may be tried for these hemiplegias and monoplegias One is the method partly of duplicated active, and partly of single active movements, used and described by some of the writers on Swedish move ments, as, for instance, by the Taylors The patient is placed in a recumbent or half reclining posture, so that he may be able to direct all the cerebral energy at his command toward the paralyzed member, and is then urged to make some simple If he succeeds to ever so slight a demovement gree, he should simply be encouraged to repeat the movement, but he should be carefully guarded against undue or too long prolonged effort simple movements are added from time to time he can do absolutely nothing, the operator should perform on the patient the desired movement, while | failure the latter fixes his attention upon the performance and tries to assist thoroughly regulated manner With light dumb bells and with the pulley-weight apparatus, all possi- A, at the same time breathing out violently

to serve an excellent purpose Such paralysis is From a cautious pursuance of such methods I have usually the result of hemorrhage, embolism, throm-seen a surprising result in a number of cases supposed to have reached the limit of improvement

Such treatment does good, not only because the original lesion may have been partially removed, but also because, by such efforts portions of the brain adjoining the centres destroyed may be made to take on new function, or possibly in some instances, the other hemisphere of the brain may be called into new activity To central spinal palsies, as well as to paralysis from brain disease, in a large measure

Another method of gymnastic treatment which I tionate to the cerebral lesion by which it has been have often employed with benefit in cases of monoplegia and hemiplegia, is to cause the patient, first, to make a movement upon the unaffected side, and then instantly to perform the same movement with the paralyzed member, following this quickly with an attempt to do the same thing with both limbs surprising the curious results that will be sometimes obtained in this way, if the leg is but little affected, We should, therefore not disregard entirely the and the patient can stand while these movements are performed by the upper extremities To exer-The course of treatment usually pursued in these cise the legs, the patient, of course, should be placed cases, in the main wise, is, at first, to do little more in an easy position, and one that will allow the than protect the patient from disturbing influences, movements to be performed with the greatest con-Exercises of this kind probably have flammation which sometimes accompanies or follows some effect in bringing the paralysed side of the it, have subsided—that is in a few weeks or months body under control of the uninjured side of the -to give absorbents and alteratives, and to apply brain through commissural channels in the spinal

For some of the arthritic neuroses, and for rheuthan this, however, should be done, and it is just matic neuritis, or muscular rheumatism, these exerhere that single active exercises, after some thorough cises are of undoubted value. I have seen three cases of a form of rheumatic neuritis affecting the sistent with safety, should be made to unite again deltoid and adjoining muscles, in which the progress to complete recovery was much assisted by an early resort to dumb bell exercises and pulley-weights Cases of this kind are best treated by using large doses of oil of gaultheria, or sodium salicylate, with hypodermic injections of morphia in the most acute stage, a little later resorting to massage, electricity, or both, and then to exercise with light dumb bells or pulley-weights Here, again, the point I wish to impress is, that such active exercises should not be deferred too long

Hysterical aphonia or apsythria (loss of the power of whispering) can sometimes be treated successfully by a species of respiratory gymnastics, or a combination of respiratory with vocal and muscular gymnastics Dr Mitchell has described a method of bringing back the voice, which is really a form of respiratory gymnastics, a method which I have used several times with success, and less frequently with Speaking of a woman who had good power over the laryngeal muscles, but could neither speak When a little headway has been nor whisper, he concluded that if he could teach her made, systematized active movements should be to speak only with a very full chest, he might secure used in conjunction with electricity, massage, and an involuntary success. Asking her to fill her lungs duplicated active movements in an orderly and several times, and when very full to keep her mouth wide open, he then had her try to sound the broad ble movements, and particularly those which are made a clear, audible sound, and was at once on the high road to cure Some years ago, with this simple method, I obtained a brilliant success with a young lady who had not spoken even in a whisper for many months I now combine light dumb-bell and pulley-weight chest exercises with this method

In certain cases the treatment by rest, seclusion. etc, can be successfully combined with that by systematized exercises After the nervous or broken- in the treatment of skin diseases by Unna down patients suitable for the treatment have progressed to a certain point, after their nutrition has been placed upon a firm basis, respiratory exercises without apparatus, or with very light dumb-bells, can be carefully begun Five minutes, or perhaps only three minutes, should be taken at first, and the time should be increased with the utmost caution recent neurasthenic case with hystero-epileptic seizures, after the patient had improved under the rest treatment, systematized active exercises were resorted to with the greatest benefit In those cases of hystero epilepsy in which the seizures are partially voluntary, or of the induced voluntary kind, the use of such exercises assist the patient in obtaining the control of herself, and the movements which enables her to resist the beginning of the attacks

Dr. C F Taylor, in the book to which I have already referred, has hit the secret of the combination of rest and exercise in certain cases

"The true remedy," he says, "is rest and exer-Let the rest be complete relaxation of all muscular effort-not the entertaining of company, sitting bolt upright, so that the spinal muscles must be constantly acting, or reclining in a 'graceful' attitude on a lounge, with book in hand, but a completely sustained position, when all the muscles must Then the exercises to follow should cease to act be short, varied, and taken with some vigor "

The now generally accepted views with reference to cerebral localization throw some light upon the manner in which systematized active exercises, or other forms of gymnastic treatment, improve or repair the nervous system, and especially the brain This fact has not been overlooked by authorities in tations of rheumatism neurology and gymnastics, as by Emil Du Bois-Reymond, Schreiber, Crichton-Brown, and others In the brain are represented both a differentiation and an integration or solidarity of function for speech, for vocalization, for particular move ments, for the special senses, for the muscular sense for organic sensations, for some of the higher faculties, as of attention and inhibition, are now, with reason, claimed to have been isolated localization of some of these, as of speech, motor, from pain and some of the sensory centres, the facts and arguments are practically incontrovertible est of terms, if brain centres which determine cer- ichthyol act more powerfully in allaying the pain than tain movements exist, the performance of these any known medication movements must develop and train not only the muscles concerned in these actions, but the cerebral | drug centres with which they are connected

ICHTHYOL IN SURGERY

Read before the Philadelphia County Medical Society, January 25, 1888

> BY EDWARD MARTIN, MD, OF PHILADELIHIA

Ichthyol was first described by Schrotter, and used obtained as a clear yellow-brown oil by distilling a certain bituminous matter found in Tyrol, and containing the fossilized remains of fishes and marine anımals By the action of sulphuric acid on this distillate, and subsequent neutralization with soda or ammonia, either the sodium or ammonium sulphichthyolate is produced. The latter compound is preferred by Unna

The ammonium sulphichthyolate is reddish-brown. clear, syrup-like liquid of burning taste and odor, soluble in water, making a clear, red-brown solution, also soluble in equal parts of alcohol and ether

The ichthyol preparations are characterized chemcally by their richness in sulphur (10 per cent), so intimately united that it can only be extracted by complete decomposition (Lartigeau), they easily take up oxygen, acting as powerful reducing agents (Baumann)

Clinically, the ichthyolates are described by Unna as being powerful antiphlogistics, causing anæmia and rapid subsidence of swelling in all tissues. This antiphlogistic effect is ascribed to the drug's action on the endothelium of the bloodvessels depriving it of oxygen in virtue of its reducing properties, and contracting the lumen of the vessels This explanation is not, perhaps, entirely satisfactory, but physiological studies have not yet given us a better one. The cornifying effect of the drug on the epithelium of the rete is undoubted

Surgically, what are the indications of the drug? Lartigeau states that it is indicated in all subcutaneous and inflammatory tumefactions, cedemas, vascular dilatations, incipient furuncles, and local manifes-

Elliot praises it highly in burns of the first and second degree (5 per cent solutions in water) as producing rapid subsidence of pain and inflammatory symptoms He finds its application to obstinate varicose ulcers associated with eczema rubrum (sodium compounds, 3 to 5 per cent) at times produc-tive of marvellous results In his hands it is also useful in cicatrices, and in a few cases of rheumatism For the and neuralgia has given immediate and marked relief

Schweninger states that in rheumatism, lumbago, In the plain-lischias, tic, gout, and migraine, local applications of

> Lorenz is astonished at the fabulous efficacy of the In acute and chronic joint rheumatism, acute muscular rheumatism, mastitis, panaritis, and confusions, a few rubbings with pure or 50 per cent ichthyol compounds are peculiarly successful in allaying pain and hastening healing. In chronic and acute while this is the rule in acute muscular rheumatism

DR AUVARD has been made Editor of the Archives de Tocologie, the well-known obstetrical and gynecological journal, published by Delahaye and joint rheumatism relief often follows a single rubbing, Lecrosnier, of Paris

The pain of gout disappears, the shining red skin becoming quickly wrinkled A beginning mastitis or panaritis is always aborted, or if fully developed the pain is much relieved. Its prompt use prevents the discoloration following contusions It immediately allays the pain of a burn, and prevents blistering Finally, a 10 per cent solution hastens the cicatrization of badly healing ulcers

compound cannot be borne and prevents irritation of

Von Nussbaum states that a single application of ichthyol i part, water 4 parts, lanolin 5 parts, has allayed the itching of eczematous ulcers which had resisted all known applications for weeks and months, and promptly brought about rapid cicatrization on being continued a few days Arthritic pains, which for weeks have made day and night miserable, are relieved at times in one-half minute after the application of a strong ichthyol ointment. In erysipelas it produces results obtainable by no other means, namely, the immediate arrest of the disease Nussbaum's treatment was first the thorough disinfection and drainage of the wound, then, if the disease continued to extend, over its whole surface a thick layer of ichthyolate and vaseline, equal parts, was spread and covered by a layer of 10 per cent sali-The erysipelas advanced not a line cylated cotton further and in a single day the swelling disappeared and the red, shining, puffy surface became yellow, brown, and wrinkled This remarkable effect you Nussbaum ascribes not to the influence of the drug as Fehleisen's cocci, but rather to a change produced in the tissues by virtue of which they cease to favor instance the growth of the microorganisms

Stelwagen has had excellent results in the abortion

of furuncles by ichthyol preparations

Agnew (D Hayes) considers the ichthyol preparations more powerful than any known therapeutical agent in bringing about reduction of inflammatory enlargements, and has had particularly good results in recently enlarged lymphatics He uses sulphichthyolate of ammonia and iodide of lead, equal parts, applied generously and covered in by oiled silk

The writer has used ichthyol in-

I Six cases of cervical adenitis, with absolutely no relief, cure being subsequently brought about by 10dine or the knife

- 2 Fifteen cases of marked inflammatory induration of the subcutaneous tissue, with invariably a speedy and in some cases almost a magical reduction, and this after other means had been tried unsuccessfully
 - In two cases of furuncles without good effect
- 4 In one case of cellulitis without marked effect till the knife was used (in this case staphylococci were found but no chains)
- 5 In four cases where pain was the most marked feature of inflammation, with complete relief in three and no effect in the fourth
- 6 In one case of erysipelas of the scalp, with ımmediate cure

The latter is so striking that it is reported in full

B C, bartender, æt 36, full-blooded Irishman Struck on the head by a bottle whilst intoxicated, December 20, 1887 Two slight wounds of the scalp, to which no dressing was applied 22d Chill, fever, nausea, great pain in the head, and swelling to a clinic, wounds were opened, disinfected, and catgut drainings provided, symptoms progressive He was seen by the writer on the second day of his Loring dilutes with water when the pure ichthyol fever, the fourth from the infliction of the wound No sleep for two nights Pulse 106, temp 103° the skin by careful washing and drying before each Violent headache, whole scalp puffy, cedematous, application and very tender, a few drops of thin pus squeezed from wounds Cover-glass preparations of blood from puncture by tenotome showed Fehleisen's chains A saline purge and iron were ordered internally On the scalp was placed a thick layer of ammonium ichthylolate and vaseline, equal parts The pain was relieved almost immediately, the patient slept comfortably, his temperature the following morning was 98°, and he was and remained well

This is not different from the results obtained by

Nussbaum

With the exception of the case of erysipelas, the writer used a 10 per cent ointment of ammonium ichthyolate in lanolin, fearing lest, in the case of stronger applications, his effects might be ascribed to counter-irritation It is possible that stronger preparations would have proven efficacious in the treatment of adenitis in which the weak ointment failed

The extravagant praises bestowed by some authors on ichthyol savor more of proprietary advertisements than scientific contributions, and the variety of affections for which it is recommended might well make one doubtful as to its complete efficacy in any single

An analysis of the cases in which it has proven serviceable will show, however, that they can be relegated to one of two classes

r Affections characterized by inflammatory enlargement

2 Affections characterized by pain of peripheral origin, probably depending on inflammation or congestion

For either of these conditions, theoretically, a powerful antiphlogistic would be indicated, so that the clinical indications for the use of the drug corres-

pond to its alleged therapeutic effect

When the surface is irritated, weak solutions (3 to 5 per cent) should be used, but when the skin is intact and the subcutaneous tissues are to be affected, pure or one-half strength ointments give the best re-In using strong preparations the skin should be washed with warm water and soap, and thoroughly dried before each application Ichthyolates can be combined with any of the ointments, or can be dissolved in water

The writer's success with the drug, even where it was not used in the most efficient manner, has convinced him that the praise bestowed on it by the Germans is well merited Where suppuration has actually taken place the weak ointment is not of service, but in the allaying of inflammatory pain and the resolution of subcutaneous induration (excepting adenitis) the results are most satisfactory

SOME INTERESTING SEQUELÆ OF A CASE OF SCARLET FEVER

Read before the Philadelphia County Medical Society, on Janu ary 25, 1888

BY A J DOWNES, MD, OF PHILADELIHIA, PA

On November 15, 1887, at 3 P M, I was asked to see B M, a boy of 7 years, then under the care of a homeopath, and said to be dying of heart disease I called immediately The boy was comatose, had been so for twelve hours The face had a characteristic pallor, the eye-lids were slightly puffy, the

pupils dilated, the breathing stertorous

I listened to the heart and heard a loud systolic apex murmur, a diastolic one at the right base, and mingling with both a peculiar whistling sound, the cause of which at the time I did not understand Examining further, I found that the eyelids had become puffy two days previous, that the feet and ankles were now swollen, and the scrotum slightly No urine had passed in twenty-four hours cepting a few scybala, forty eight hours before, the bowels had not moved in seventy-two hours

The child had scarlet fever five years before I told the father that the boy did have heart disease, but that he was dying of uræmia Shortly after 5 PM the boy was dead The following morning Dr Martin Rively and myself made a post mortem examination The specimens I show are

the heart, kidneys and a piece of the liver

So advanced cardiac lesions in a child of this age are far from common The ventricles are both hypertrophied and the cavities dilated, the right con-The curtains of the mitral valve are affection thickened and fibrous, the posterior leaflet is exceedingly contracted and shows above it a recent almost natural course The aortic curtains are a beautiinflammatory area ful picture of an insufficient valve The whistling sound I heard during life must have come from the tricuspid valve The hypertrophy of the muscular elements of the ventricle, with the marked distention to which the cavity was subjected, surely allowed sufficient leakage to cause this sound

On account of its so late recognition and its undoubted influence in enhancing the cardiac condition | middle-ear affections, is by no means uncommon, and the state of the kidneys is exceedingly interesting Even microscopically the kidneys show changes fallacy of supposing that a chronic otorrhœa is best which must have been going on for some time pale cortex and the eversion of the cut edges indi-Under the microscope we find evidence of colored, æt 15 years long existing changes, sufficient to warrant the as- attack of measles, following which came a discharge sumption that in the long-ago attack of scarlet fever from the ear and almost complete loss of hearing the kidney changes began The tubules are swollen, She was always sick Headache was a frequent distorted, and full of casts The epithelial cells affair, and at the time of my visit she was experihning them are somewhat granular and smaller than encing an unusually severe attack. There was some normal with their nuclei becoming indistinct Long fever, constipation, loss of appetite, rather slow existing changes therefore We find also recent pulse Bromide of potassium was given for the headconditions

The glomerules are swollen and congested and in their vicinity an infiltration of small indifferent cells A very characteristic glomerulo-nephritis of recent night. I now examined the ears and found the left The cause in this case of anuria and conse- meatus filled with pus quent urremia And the history points to this for that she had suffered from the ear disease, with dis-

the boy, although not well for a few years back, was comparatively so For two weeks previous to his death he was confined to his bed, and undoubtedly during this time he was suffering from a glomerulonephritis which, adding itself to an already damaged kidney, precipitated an attack of uræmia

Additional proof that the boy's kidneys were not normal prior to his last sickness is not wanting bladder, post-mortem, contained about two ounces -twenty-four hours' urine-of this I collected one It contained a large amount of albumen but no sugar, round and columnar epithelial cells showing fatty degeneration, a few epithelial casts containing oil globules and some free oil A few weeks nephritis could not cause this urine

The liver changes are secondary to the heart con-Under this microscope it shows both fatty

infiltration and degeneration

In concluding, I would recall the points that in-First The extensive terested me in the case cardiac lesions caused by scarlet fever, occurring in a child under 2 years Second The late recognition of the heart, the non-recognition of the kidney con-Third The occurrence of acute inflammation—the glomerulo nephritis almost typical of scarlet fever-in an already damaged kidney Finally May I not call attention to this case as showing to what extent the sequelæ of scarlet fever may advance when not recognized and treated history of the case proves such to be the fact Eight homeopaths in succession had charge of the Over a year boy for four years prior to his death The one in ago one had diagnosticated diabetes attendance before my visits had recognized valvular But the kidney lesions had escaped them Apparently this proves that the case ran an

ABSCESS OF THE CEREBELLUM CAUSED BY DISEASE OF THE EAR

BY THOMAS C SMITH, MD, OF WASHINGTON D C

Disease of the brain caused by the neglect of the case to be reported is another instance of the

The treated by being let alone

On August 29, 1887, I was asked to see M W, When an infant she had an ache, and the bowels were moved by suitable means At my next visit I learned that the girl had had convulsions after my visit, and had passed a sleepless Her mother informed me

charge, ever since the attack of measles, as already mentioned At times the discharge of pus would cease for a while but her symptoms did not seem to be modified thereby She did not think anything could be done for the ear disease, consequently, nothing had been done. The mother was given to understand that the headache and convulsions were due to the ear disease and an unfavorable prognosis The ear was syringed and an astringent was given used to try to influence the diseased middle-ear tissues Chloral at night secured sleep, and after a week my instrument, as now arranged, leaves both hands of visits were discontinued On September 14, the girl came to my office with her mother, and the ear was examined The purulent discharge was not quite so free, but the meatus was so much obstructed by granulation-tissue that it was impossible to get a view of the deep portion of that tube condition of the girl was so bad that I did not think any treatment would avail much Still, she was I did not see her again until the 12th of On the 14th she was easier, but she was disposed to be drowsy On the 15th coma existed the sinus and she died about the middle of the day The diagnosis of intracranial abscess had been made paralytic symptoms existed at any time

Brain surgery is making such great advances, that the time may come when all intracranial abscesses and tumors will be subjected to the same treatment as when they occur in other locations In view of the fact that the existence of abscess was so clearly established in this case, the question arises, Why was not the skull trephined and the abscess sought out and opened? In the light of the symptoms presented, I answer the question by asking another Where would the surgeon have applied his trephine? And with the post-mortem evidence before us, I ask whether an operation would have been correctly located before the patient was in extremis?

The autopsy was made by Dr Lamb, and I append

his notes

"Necroscopy — Head alone examined Left meatus auditorious externus occupied by thick, purulent matter of dark, rather bloody hue Dura mater normal, except on posterior surface of petrous portion of left temporal bone, where the adhesion was a little greater than normal around an opening in the bone, this opening was one-quarter of an inch in diameter and communicated with the tympanic cavity, this cavity, again, was enlarged by progressive excavation of the bone, into a chamber an inch in length, and of corresponding breadth and height Cerebrum normal Left hemisphere of cerebellum, anterior half converted into an abscess "

KASCHAN HOSPITAL -A few years ago three Russian female physicians founded a hospital at Kaschan, Persia, for Mussulman women The extwelve months 15,000 patients have been treated

MEDICAL PROGRESS.

THE TELEPHONIC BULLET-PROBE —At the meeting of the Surgical Section of the New York Academy of Medicine on January 9, Dr J H GIRDNER read a paper on this subject. In the past year he has perfected the instrument that he described a year ago, and now operates it by a current of electricity extracted from the body of the patient himself the operator free, and shuts out all sound except that heard when the bullet is touched Dr Girdner re-

ports the following case

A musket-ball had lain between the tibia and fibula for twenty-two years A long, narrow, tortuous sinus The general had been discharging for a year When an ordinary probe was passed, hard substances could be felt in many places, but you could not tell if bone or bullet ordered tonics and good nourishment, and the ear was being probed The porcelain probe could not was to be cleansed with astringent and antiseptic have been marked by the lead owing to thick crusts of salts of lead with which the ball was covered, even the present month She was in bed suffering from if it could have been brought into contact with the bullet, which it could not, owing to narrow places in Bone and other tissue were felt as the probe passed to different parts of the wound, but no No response was heard in the telephone until the leaden bullet was touched, then an electric current passed The case is interesting from a surgical point of through the telephone, and as often as this current was made and broken, by touching and removing the probe from the lead, so often was there a vibration of the diaphragm, and consequently a clicking and scraping sound heard in the telephone, in other words, the patient's body was converted into an electric battery, the body corresponded to the cups, its fluids and heat to the battery fluid, the steel bulb immersed in the mouth to the zinc, let us say, and the lead when it was touched, to the carbon, and thus our battery was completed, a current obtained, and the metal diaphragm made to vibrate

The advantages of this instrument over all others beneficial even supposing the abscess to have been at once appear, when it is remembered, that in its use the accurate sense of hearing is substituted for that of the sensation communicated to the hand, which is always unreliable, for no one can tell if a hard substance felt in a wound be bone, metal, or some other hard tissue The porcelain-tipped probe was made with the hope of overcoming this difficulty, but after ample experience with the Nélaton probe, both in my own hands and in those of others in my presence, I am certain that, unless the bullet is perfectly clean from grease, lead salts, etc., and very favorably situated, it is not possible to obtain lead markings on the porcelain tip which can be relied upon to direct our operative procedure Let any one hold a bullet in the hand, and probe it with a Nélaton probe until the markings of the lead on the porcelain point are perfectly distinct, and he will find that it requires an amount of force and pressure in rubbing the lead which he will rarely be able to make, even in the most favorable cases of gunshot-wound None of the above conditions, which make the Nélaton probe periment has met with great success, and in the last useless, in any way interfere with the perfect working of this new probe, for the slightest touch of the bullet

with the probe causes a loud and unmistakable sound Another great advantage is, that in the telephone a sharp, slender, steel needle may take the place of the blunt probe, and then no tract is necessary in probing, the needle, rendered aseptic, may be thrust into the tissues like a hypodermic needle, with little pain, and no danger to the patient, as has been verified in actual practice, and when the bullet is struck, you have only to loosen the clamp-screw and remove the handle, allowing the needle to remain fast in the tissues, with its point still in contact with the missile, and it serves as a perfect guide in cutting down on the bullet -Medical Record, Feb 4, 1888

SALT IN MILK FOR CHILDREN -DR JACOBI SAYS that the physiological effect of chloride of sodium is very important, no matter whether it is directly introduced through the mother's milk, or added as a much as 15 grains in twenty-four hours, the only condiment to cow's milk, or vegetable diet of the latter contain more potassium than sodium, and neither ought ever to be given, to the well or sick, without the addition of table salt of that which is introduced may be absorbed in solution, another part is, however, broken up into another sodium salt and hydrochloric acid serves directly as an excitant to the secretion of the glands and facilitates digestion Therefore during diseases in which the secretion of gastric juice is interfered with, or in the beginning of convalescence, when both the secreting faculties and the muscular power of the stomach are wanting, and the necessity of resorting to nitrogenous food is apparent, an ample supply of salt ought to be furnished excess of acid which may get into the intestinal canal unites with the sodium of the bile in the duodenum, and assists in producing a second combination of chloride of sodium, which again is dissolved in the intestines and absorbed Its action in the circulation is well understood it enhances the vital processes, mainly by accelerating tissue-changes through the elimination of more urea and carbonic acid

A very important fact is also this, that the addition of chloride of sodium prevents the solid coagulation of milk by either rennet or gastric-juice The cow's milk ought never to be given without table salt, and the latter ought to be added to women's milk when it behaves like cow's milk in regard to solid curdling and consequent indigestibility

Habitual constipation of children is also influenced beneficially, for two reasons not only is the food made more digestible, but the secretions of the alimentary canal, both serous and glandular, are made more effective by ats presence -Archives of Pediatrics, January, 1888

Tribromphenol, an Antiseptic —Grinem reports his experience with this substance as follows It is a combination of bromine with phenol, and is a mals, has used galvanism of the thyroid in the white crystalline powder, very insoluble in water, treatment of epilepsy. Of 7 cases that he reports, easily soluble in alcohol, ether, chloroform, and in 2 there was an evident diminution of the epileptic glycerine, carbolized solutions, and dilute spirits of the cure has lasted for several months -L' Electrowine It is dissolved by the intestinal secretions, therapie, January, 1888

combines with sulphuric acid, and appears in the urine as a sulphuric compound It is not escharotic, but powerfully stimulant to granulations, it does not attack the unbroken skin

It was used in gauze dipped in 2½ per cent solution, with good results, in tamponing wounds and cavities, it is well adapted as a stimulating tampon for abscess cavities, but should not be used in the pharynx, mouth, or nares

In experiments upon bacterial cultures a 1 per cent solution sterilized septic matter in thirty minutes, in 3 to 1000 solution it sterilized gelatine A small quantity added to urine prevented cultures The writer gave this substance in decomposition three doses of 1½ grains each, to a patient suffering from tænia, with good results, the whole was given within an hour and a half Personally, he took as Both effect being a slightly uncomfortable feeling in the abdomen, and an unpleasant taste

The use of this substance seems indicated to stimulate granulations, and, by virtue of its insolubility in acids and its solution in alkalies, as an intestinal antiseptic - Deutsche medicinische Wochenschrift, Dec Thus 1t | 29, 1887

> SULPHIDE OF CARBON IN ELEPHANTIASIS —DR P Anthonisz, of Ceylon, gives the results of the use of sulphide of carbon in elephantiasis, both acute and chronic, as tried by himself and a few of In some of the acute cases, the his medical friends reduction of swelling was prompt and complete, in others it was gradual but satisfactory In one, a case of thirty years' standing, a year's treatment, begun when the legs were as large as the man's waist, left them about the size of his thighs dose mentioned in the latter was two 2-grain pills per diem, to be continued for a lengthened period, except when the drug irritates the stomach, as it will do from time to time When the ill effects have passed, the medicine should be renewed writer adopts the theory proposed by Dr Manson, of Amoy, some years ago, that the disease is due to the presence, in the blood, of the filaria sanguints He believes that the remedy is efficient by hominis reason of its sulphur ingredient and its power to prevent the parasite from multiplying in the body, which, according to Dr Manson, it does with amaz-It will be remembered, that in acing rapidity counting for the presence of the filaria in the blood, the theory of Dr Manson included the novel proposition that the mosquito might carry in the parasite with his proboscis, and deposit it in tissues whence access to the blood could readily be obtained -British Medical Journal, Dec 24, 1887

GALVANIZATION OF THE THYROID IN EPILEPSY— SIGHICELLI, having noticed that thyroidectomy produced convulsions of an epileptiform nature in anitreatment of epilepsy Of 7 cases that he reports, It is dissolved but little by access A third case was completely cured, that is,

CHICAGO, ILLINOIS

SATURDAY, FEBRUARY 18, 1888

XERODERMA PIGMENTOSUM

At the first meeting of the New York Academy of Medicine in February, DR R W TAYLOR read a paper on this subject, on which he is the recognized authority in this country The paper was based on the results of his observation and study for fifteen years, and was devoted more particularly to a consideration of the malignant neoplasms to the formation of which the disease tends in its early stages They that are familiar with the literature of this subject know that the disease is peculiar to childhood, that it is multiform in its clinical characteristics, and indelible in its disfigurements, and that it was first described by Hebra and Kaposi in 1870 ing to Dr Taylor there are now 39 cases on record The first cases reported in this country were the 7 reported by Dr Taylor in 1877, and further described in 1878 (Vid Trans American Dermatological Association) Three of the cases occurred in one family, and two in another family closely related to the first With one exception all the cases were in The boy that had the disease was attacked with mumps when about 7 years old Resulting from this attack was an abscess that had to be opened, the wound thus made never healed, but extensive ulceration followed, which finally involved the coats of an artery, and thus caused uncontrollable hæmorrhage, from which the boy died other child died of marasmus, and a third was accidentally drowned

In the 7 cases reported by Dr Taylor all the has a peculiar immobility of expression clinical features of the disease were portrayed

added certain polymorphous neoplasms that are primarily benign, but that are likely to degenerate into malignant tumors. The disease seems to be one of early childhood, and in most of Dr Taylor's cases it began at about the age of 7 months, in one case only did it begin so late as the 14th month Of the characteristics of the disease the prodromal erythema is to be emphasized, its usual seat is on the face, under the eyes, it may be easily mistaken for sun-burn This hyperæmia lasts from one to three months, and as it gradually disappears the pigment spots begin to appear. These affect the face and exposed parts of the neck and extremities, after extending as low as the third rib on the chest, and up to the elbows on the arms varies from that of a pin-head to a lentil, resembling ordinary freckles, and not elevated much above the Among these are the red or telangiectasic spots, in which capillary vessels can be seen with a strong glass The prodromal erythema is not so marked on the hands as on the face, there are no marked local or subjective symptoms, such as burning or itching, and the general health remains good The lesions are always characterized by alternating exacerbations and periods of inactivity, so that the course of the disease is more or less erratic

The period of the pigment-spots and telangiectases is chiefly that of early childhood, and these two orders of lesions are peculiar to the stage of hypertrophy The atrophic changes usually appear at the end ofthe first year The atrophy is not symmetrical, as a rule, and varies greatly in extent and intensity in different subjects, while it is not commonly so wellmarked on the extremities as on the face atrophy of the skin develops in accordance with the atrophy of the blood-vessels of the telangiectasic spots It is especially apt to affect the eyes, nose and mouth, causing ectopion, with its attendant evils, and deformity of the nasal and oral cavities often hypertrophic changes are taking place at the same time as the atrophic The face presents a mottled appearance and, in addition to the freckles and red spots, there are white patches varying from 625 cm to 25 cm in diameter The skin is inelastic and like parchment, or seems as if it is coated with inflexible collodion The appearance not infrequently resembles the cicatrix of an extensive but superficial burn There is an almost total absence of the normal secretions, and the countenance often The cases, however, the atrophy is much less marked than affection consists essentially of telanglectasis, pig- in others, and it is always less prominent upon the mentations and atrophic changes, to which are super- hands than on the face This atrophic condition, in

general, is not unlike that met with in senile atrophy years Dr Jacobi has used it with satisfactory results of the skin

While the atrophic changes are to be dreaded, on account of their liability to result in hideous deformity, the keratosic or warty patches that eventually grow from some of the pigment-spots are liable to degenerate into malignant growths In 3 of Dr Taylor's 7 cases epitheliomata were found, and the statistics of all the cases recorded seem to show that in this disease the greatest malignity is exhibited under the age of 10 years, nearly as great between the ages of 10, and 20 and after that there 15 a diminished tendency to malignity It is certainly a singular fact that epithelioma should develop in such young subjects

In regard to treatment, Dr Taylor says that intelligent medication, extending over several years, has hitherto always proved quite ineffectual, and no case of the disease has ever been cured In the treatment measures should be taken to keep the skin at rest and free from all sources of irritation, and all pigmentation warts should be removed as soon as possible with the spoon All larger tumors should also be extirpated, and the subjacent tissues thoroughly scraped, if necessary to the bone or periosteum

According to some authorities most, and to Cohnheim, all malignant tumors, occurring at any time of life, are the result of embryonic cells not undergoing their accustomed changes, and remaining behind in normally developed tissue, and if this view be accepted, it will sufficiently explain the appearance of these malignant growths in early childhood, as was remarked by Dr Jacobi Furthermore, the fact that the blood-vessels are largely increased is no doubt the result of the embryonic tissue remaining, and these blood-vessels are not in a normal condition Dr Jacobi thinks it probable that the occurrence of spontaneous thrombosis may explain the disappearance of the red spots and other phenomena in the It seems, then, as if there is an arrest of the metamorphosis of embryonic tissue, and if this be the case, Dr Jacobi suggests that in the treatment it may do good to increase the quantity of normal connective tissue, if possible, and thus fortify the parts against the further development of abnormal growths For this purpose, provided the supposition be correct, there are two remedies that suggest themselves as being specially indicated first, arsenic, By the and second—and better still—phosphorus irritation excited by suitable doses of these agents it seems possible to cause a good solid, normal nutrition in the connective tissues Phosphorus favorably influences the normal growth of bone, and for some tical chemist, but simply a certificate of ability to

in caries and other bone diseases, finding it of special service in cranial rachitis The phosphates and other compounds are of no value, phosphorus itself must be used It may be given in oil or emulsion, in doses of or grain twice a day, and it must be used for a long time

Dr Jacobi's suggestions are valuable and practical, and it would be well if some one were to institute a systematic course of medicinal treatment in accordance with them in future cases At the same time, surgical measures are of decided benefit in controlling some of the more serious results of the disease, and, contrary to what might perhaps be expected, as a rule the tissues heal well after the removal of the new growths

THE NEXT MEETING OF THE ASSOCIATION

This year will witness a change in the programme of the general meetings that has been necessitated by the constantly increasing number of Sections into which the Association has been divided Heretofore the Chairmen of Sections have read addresses before the general meetings, but according to the rule adopted at the last meeting, these addresses will in the future be read before the Sections eral meeting the President's Address will be listened to on the first day, and for each succeeding day a single address will be delivered by members of the profession especially selected for this purpose

The selections made this year will surely meet with universal approval Professor Roberts Bartholow will address the Association on the second day special topic of his address will be, "How Therapeutics may be made an Exact Science—Illustrated by Examples" On the third day, Dr E M Moore, of Rochester, will deliver an address on Surgery, and on the fourth day Dr H P Walcott, of Boston, will deliver a general address on State Medicine

We give in another department a programme of the general meetings of the next session of the Association

FEMALE PHARMACISTS IN ITALY

The Minister of the Interior, of Italy, having had his attention called to the fact that about 3,500 places in the Kingdom have no pharmaceutical service, because young pharmacists refuse to go into the rural districts, has asked the Minister of Public Instruction to admit women to the study of pharmacy It is not asked that they be given the diploma of phamaceupractice pharmacy vent the great inconveniences of the illegal practice of pharmacy, and will provide pharmaceutical facilities for communities in need of them

It is to be remembered that in Italy, as in other European countries, the drug stores are under government control and supervision—the druggist is a government appointee, and one cannot own a drug store unless he is a pharmaceutical chemist and gets a government appointment The number of druggists and drug stores is proportioned to the number of inhabitants, both in the cities and in the country, so that the druggist is sure of a legitimate trade, and does not have to eke out an existence by selling patent medicines, toilet articles, paints, kerosene oil, cigars and chewing-gum The people are likewise protected by government supervision as to the purity of the drugs, and as to the competency of the drug- A CASE OF EPILEPSY CURED (APPARENTLY) BY THE gist to prepare them

This is a further illustration of the fact that while some of the European governments may be "effete monarchies," as our newspapers are pleased to call them, they still act on that sound principle of common sense, that the health of the people is the nation's wealth

A QUESTION OF CRIMINAL NEGLIGENCE

A number of years have now elapsed since the question of color-blindness among railway employés was first brought before the public Since that time so many examinations have been made of the colorvision of railway employés, so many of such employés have been found to be partially or totally color-blind, and so many accidents have been caused by the color-blindness of locomotive engineers and other railway employés, that it becomes a serious question, are not railway companies guilty of criminal negligence-negligence of ordinary precautionswhen they place their trains in charge of color-blind men, or when they employ color-blind men for positions in which, on account of their defective vision, accidents may result? The facts are so many and so clear that it would be idle for a company to set up the defense that testing the color-vision of their employés is an extraordinary, not ordinary precaution

There is another question in regard to these tests for color-vision Are the examinations made, in addition to the Holmgren tests, with colored lights in a dark room? Railway locomotive engineers say that while some men can easily distinguish red and green colors by day, they cannot distinguish red and green lights at night as they should-and conversely

It is believed that this will pre- also seems to be the case that while some men cannot distinguish red and green as such by day, they see that there is a difference, and are guided by it, but on a cloudy, foggy or rainy night, they sometimes find it impossible to make out the real color of the light shown, and are often guided by the better vision of the fireman

SOCIETY PROCEEDINGS.

CHICAGO MEDICAL SOCIETY

Stated Meeting, January 16, 1888

THE PRESIDENT, W T BELFIELD, M D, IN THE CHAIR

DR E J COLBURN read the report of

CORRECTION OF AN ERROR OF REFRACTION

(See page 189)

DR E L HOLMES The report, I think, speaks for itself, I do not know what can be said of much interest in addition We simply know the fact that, in very rare cases, the proper adjustment of glasses has cured epilepsy We know that paring a corn may give relief, but that does not prove that corns are often the exciting cause of epilepsy said to be very rare cases in which small shoes with high heels have produced a general nervous condition-headache and disturbance of the muscles of It is useless to adjust glasses in the hope of cure until the general nervous condition has been relieved by "common sense shoes" A contracted prepuce may be, although very rarely, the exciting cause of epilepsy So we can go through the whole series of remote nervous irritation producing the trouble we call epilepsy There are some cases that are exceedingly interesting but at the same time rare Many of the cases that are reported are simply coincidences It shows us, however, how important it is in nervous trouble to seek the cause and to have the eyes relieved as far as possible by proper glasses This may not only cure epilepsy, but also other nervous troubles

DR F C HOTZ The case reported bears on a very interesting question which only within the recent past has attracted general attention was the only case and we had to judge the result of the treatment on its own merits, that is, if it was a single isolated case, without any other experience to support it, of course we would be rather reluctant to admit the doctor's conclusions, even perhaps in the modified form, as apparent relief, especially as, in the history of this case, besides the adjustment of glasses other means have been used which are known ta give temporary relief in such attacks tunately for the reporter and fortunately for us, similar cases have been reported, especially through the methodical investigations which Dr Stevens, of New It | York, has carried on for the past ten years It was

he who conceived more clearly than anyone else, I previous treatment had almost entirely failed to rethink, the idea that functional disturbances in the lieve the patient and nothing had been accomplished eye, an overtaking of the muscles adjusting the sight when he adjusted the glasses, and subsequently to or controlling the motions of the eyeballs, have a that the patient was apparently cured. The inference far-reaching influence on the whole nervous system of is fair that the adjustment of the glasses was the the human body, and are among the most prolific means of curing the patient. In reference to the sources of nervous diseases It is well known that irritations of the eye go far to excite reflexirritation some- errors of refraction, in insufficiency of the orbital where else, I need only refer to the general disturb- muscles, and of accommodation, actual or relative ances created by an attack of glaucoma or iritis I believe, in cases like the one reported to-night, the ducing peripheral and central nervous symptoms. In general nervous disorder is not caused by reflex irritation (for there is no irritation in the eyes), but it is the result of an overtaxing of the nerve forces Every human organism is endowed with a certain amount of nerve force, in some this force is largely in excess over the amount necessary for all demands of the physiological functions, in other persons, however, it is barely sufficient. It is this latter class, which has no reserve force to draw upon, that constitutes the large army of so-called nervous people Now if in such a person, to whom the nerve force has been scantily measured out, the adjustment of the sight or the harmonious movements of the eyeballs are executed with difficulty, requiring a greater duced vomiting I corrected a trifling astigmatism nerve stimulus than under normal conditions, the eyes appropriate a larger portion of the nerve force than they are entitled to, they continuously drain, as it were, the resources of the nervous system, exhausting the supply of nervous force which ought to go to other parts of the organism, and under these conditions there a very trifling exciting cause may more commonly still, by insufficiency of ocular produce marked neurotic disturbances

When we read the published observations of Dr Stevens, based upon 2,000 cases, we cannot help admitting that there is a great deal of truth and logic in his conclusions, even if we assume that a pioneer ternal, he cured 50 per cent, 40 per cent were rein a new field is unduly enthusiastic, and perhaps lieved, and only to per cent unrelieved carries his conclusions a little further than the actual facts will admit on cooler reflection and larger expe-We owe Dr Stevens a great deal for pointing out this subject, it is as interesting to the general practitioner as to the oculist, it will induce the practitioners to pay more attention to the diseases of the It is a field in which the geneye than they used to eral practitioner and the specialist can very profitably cooperate, because these cases usually consult is in the internal rectus muscle, which is determined the general practitioner first, we do not see them by examination with prisms, he punctures the exterunless they have marked disturbance of the eyes, and thus we often accidentally relieve other troubles suppose every oculist has had an experience similar to my own, that patients who have been forgotten by us meet us years afterwards and thank us, saying that by adjusting glasses or relieving some other functional disturbance of the eye they were relieved of chronic headaches or other nervous disturbance systematic investigation of the relation of eye-strain and nervous disorders which I think is the great merit of Dr Stevens, and such observations as have been reported to-night are valuable contributions to confirm Stevens' conclusions

The report that Dr Col-DR W F COLEMAN burn has made is exceedingly interesting, and if I understand him aright in regard to the treatment, all ation, which consisted of puncture of the external

cause of eye-strain, we see it in three directions In But All oculists agree as to the effect of eye-strain in promy own experience correcting insufficiency of muscles has relieved most severe and persistent headache, such an amount of headache as to induce the general practitioner to send the patient to me for examination of the eyes, to determine whether there was cerebral disease, and there would not be found any optic nerve trouble, but an error of refraction or insufficiency of ocular muscles which, relieved by glasses, Migraine is another disease relieved the headaches which is frequently relieved by correction of errors A few days ago a patient came to me of refraction who had persistent nausea occasioned on every attempt to read, and which, if persisted in, almost inand the nausea was at once relieved

As to the cause of epilepsy if peripheral irritations, as phimosis, calculus of the bladder or irritation of the ovary will produce an epileptic seizure, why not such a constant source of irritation as an eyestrain caused by an error of refraction, or, possibly muscles?

As to Stevens' results he claims that of 64 patients on whom he operated on the ocular muscles, dividing the internal recti for insufficiency of the exney, who is a follower of Stevens, has operated on He has treated 16 patients for epi-200 patients lepsy (8 by operation), cured 3, and relieved 4 out of 5 of the remainder Dr Stevens' claim seems to us as professing too much, but when we take his results into consideration we can scarcely be totally skeptical

I suppose his method is that when the insufficiency nal rectus muscle, leaving the inferior and superior border of the muscle intact if there is only a limited amount of insufficiency, say 5° or 10° dispute his clinical results, but what astonishes me is the claim of insufficiency of the internal rectus being relieved by a puncture of the external rectus not say that it is impossible, but it astonishes me that a simple puncture of the external rectus will reheve That is the means an insufficiency of the internal which Dr Stevens resorts to to relieve his patients He finds errors of refraction and accommodation and In one instance, in an asylum, corrects those errors he selected 12 cases of epilepsy with dementia Those 12 cases had, in the month previous to his operation, 170 attacks of epilepsy, but subsequent to his operrectus muscle principally, they were relieved to the This statement is corroborextent of 75 per cent ated by the Superintendent of the asylum

These are facts, whatever the explanation may be, that we cannot ignore and cannot be altogether skep-I have great respect for these statements, and full confidence that the claim by the reader of this evening's paper of an apparent cure of epilepsy is the direct result of the correction of an error of refraction, and I think from the course of treatment pursued before the error was corrected that the inference is very fair

DR CASSIUS WESCOTT As I had the pleasure of seeing the case reported by Dr Colburn, I would like to emphasize one or two points I think there can be no doubt as to the patient's epilepsy, his attacks as described and as witnessed by myself were quite characteristic In some of his attacks he was, no doubt, unconscious, but in others he probably did not lose consciousness But the condition of unconsciousness is not now regarded as an absolutely es- ness sential feature of an epileptic attack I have seen patients in the Illinois Eastern Hospital for the Inmal, who were evidently conscious throughout some of those attacks

As to the treatment of this patient before he got his glasses, I think it could have had very little effect after the adjustment of the lenses, because the doses of bromides were small and discontinued entirely before the glasses were used I believe that any person of a neuropathic tendency may have epilepsy induced by any persistent local irritation, and those of us who have experienced eye-strain know full well what an annoying irritation it is

The theory of Dr Stevens seems to me quite rational, but regarding the cause in this case as simple local irritation, I think it was quite sufficient, for I had the opportunity to witness the distress the paglasses, and his general nervous irritation was clearly The flushing of the countenance and dis- recognize him tension of the vessels of the head was quite notice- much the same manifestation, though in less degree able

Dr J E COLBURN hypermetropia and astigmatism, and any error of refraction that increases the effort of the ciliary muscle, also increases the action of the internal rectus, and almost invariably we get with hypermetropia during these years more or less preponderance of the internal rectus Of the 375 cases of hypermetropia that I have tested over 95 per cent showing a preponderance of the internal rectus the external, but the comparison between the two tages making it either a preponderance or an insufficiency, full recognition three weeks, witnessing his daily office work The a fit operation is simply taking the conjunctiva up, cut-

ing it completely, but leaving it adherent above and below I know that this will relieve as high as 12° of insufficiency and many times give a result of di-In a case that I recently operated on in vergence which there was hystero epilepsy, a marked case which had been under the treatment of some of our best specialists, the result was a - 2, and I only cut the central fibres I know it because when I did the operation I felt the attachments above and below The operation was done four weeks ago, up to the time of the operation she had had repeated seizures. but has had none since A case that I tested nine months ago has had but one seizure since, although she had been having them almost constantly before In this case the treatment was given without the patient being conscious of our object in giving her relief, she had never had any consultation with her physician about glasses giving her relief, and nothing was said to her by the family

In regard to the statement of no loss of conscious-It was the patient, not I, that made the state-I saw him in one attack in my office when I knew he was unconscious He was under treatment sane, who had frequent attacks of petit mal and grand in one of the best Western asylums and had all the care that could possibly be given, but immediately on resuming his work the seizures returned with their old violence After he came under my observation he attempted in my office to do a little writing, but just as soon as he tried to do anything of that kind I could see the pulsation in his head and neck, the capillaries would show marked distension and he would become morose and sullen, then he would go out and wander around the streets for a few hours and have a seizure on the street or at his boarding-But since I put him under treatment up to this time he has had but one seizure, and from a flushed, red-faced, brawny looking fellow, a man who looked as though he would have all the bad impulses and habits of drink (many times I thought he must tient suffered from attempts to use his eyes without be under the influence of opium or liquor), he has improved until people who knew him before hardly When he was at school there was

I do not claim that errors of the recti muscles are It is a well-known fact that the cause of many cases of epilepsy, but I think that in certain cases it is so I have known Dr Stevens' work for fifteen years He was my instructor in Albany in 1873, and I have seen his work at intervals While he is an enthusiast, he is honest and candid, and his work will show him to be conscientious and an accurate observer during the past year, with this in view, I have found ber that a few years ago it was almost a disgrace to I rememspeak Dr Stevens' name, it would be said, "Oh, Not necessarily a lack of strength of he's the prism crank!" He labored under disadvan-The question of reflexes had not received its But I think any one who has sufwhichever you choose to call it Regarding the fered from error of refraction can easily see how an I had, two years ago this irritation of this kind can produce cerebral congesspring, the pleasure of being with Dr Stevens two or tion and this go on until it explodes in the form of

I remember a case of a boy of 18 or 20 years who, ting through it and then exposing the ocular end of during the latter part of every term of school, would the tendon, grasping this with a pair of forceps and suffer from nervous sick headaches until he would snipping away the central portion of it, not detach- get into a hysterical condition and have to leave

Biomides and chloral were tried, but all of his school life was maired by this defect, and it was not until the error of refraction was corrected that he was able to do systematic work

I saw many of Dr Stevens' cases of epilepsy, and it was wonderful to see the results of two or three weeks' treatment Patients would come theredrooling, idiotic children, young men and women, and their whole physical condition would seem to be I remember a child, in appearance about changed 13 years of age, but in reality 18 years old She was drooling and idiotic-looking, and in three weeks I saw the child and failed to recognize her Her head was up and her whole bearing changed, and she was bright-Before that she would come into the room sullen, suspicious and angry. It seemed almost a marvel, and I do not wonder that Dr Stevens is many times seemingly extravagant in his statements

In regard to failure to cure, I think it is well established that nervous cases are the most difficult to There is a certain condition, a neurasthenic tendency acquired or hereditary, and when the predisposing cause is removed there may be for a long time a slight irritation. I have noticed many times in treating cases of chorea, directly due to errors of refraction, that the patient would show marked signs of movement every time the menses came on, showing that a little disturbance throwing the system out of its usual routine would bring it about

I call to mind a chorea patient that I first saw on She was with two women who got her a street-car in and out of the car as well as they could There was something about the position of her head and eyes that attracted my attention As they were evidently poor people, I handed my card to them They called upon me in the course of three weeks quired the efforts of the father, mother and sister to get the child into the office from the time of her first visit and two weeks following her full correction, H a = +2, +1 ax 90, the chorea had almost disappeared-so much so that a person unacquainted with her would hardly notice the unusual motions, and within a year there were no choreic motions except a nervous movement of Before that she was fast getting into an epileptic condition Now she is perfectly well, using liver, and was hard to get at, that even if a suture In her case I was obliged to do tenother glasses omy to relieve 80° insufficiency In the case of Mr T I did not do tenotomy, as I was able to overcome I had plenty of time and I practhe insufficiency ticed him with prisms for a month or six weeks and then taught him how to do it I would again call attention to the intimate relation between hereditary nervous headaches, chorea, epilepsy and insanity, to the hereditary transmission of ocular defects and their resulting irritations, and to the apparent frequency with which they occur in the same patients

(To be concluded)

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, December 8, 1887 THE PRESIDENT, T M DRYSDALE, MD, IN THE CHAIR

(Concluded from page 186)

Dr M Price exhibited a

KIDNFY REMOVED FOR GUN-SHOT WOUND

The patient, a young girl, was handling the weapon when it exploded, the ball entering in front, on the right side, and passing through the liver and kidney and burying itself in the spinal muscles At the time of the operation, twenty-four hours later, the pulse was 150, the temperature 103°, peritonitis had set in and the patient was in a collapse. An incision six inches long was made and arterial blood was seen escaping from the kidney, which it was thought best to remove The liver wounds were dry and not oozing Rapid improvement continued for nine days, but there has since been a rise of temperature, and now, the 19th day, temperature is 100°, pulse 108. and all doing well

DR KELLY said that Dr Price would have to defend himself better for removing that kidney The indication was almost as great for removing the liver, which the ball had also traversed The hilum was a half inch distant and a suture would have been safe and would have checked hæmorrhage I thus stopped the flow following the puncture of a trocar in a case of hepato-phlebotomy which I performed a few weeks I think Dr Price will find sufficient evidence for this late rise of temperature in a focus of suppuration around the ball in the lumbar muscles

DR J PRICE remarked that a large quantity of arterial blood had been voided from the bladder a few Within two months hours after the injury this hæmorrhage was irregularly recurrent showing its kidney origin, and that large vessels about the hilum of the kidney had been wounded Stitching of the kidney would not have been sufficient—incision and ligation was out of the question All the indications were for removal diagnosis had been clearly made of renal injury

DR M PRICE said the kidney lay far up under the could have been put in the anterior wound it would have been utterly impossible to have reached the posterior one, excepting by another incision through the back, besides this, the blood welled up so freely that is was not possible to see exactly what he was doing, and he had to trust to his sense of touch He could not account for the high temperature at this late date, excepting it be from the collection of pus at the end of the tube, which was not removed, as it should have been

DR B F BAER presented the specimen and read the following report of

A CASE OF TRAUMATIC HÆMORRHAGE INTO AN OVA-RIAN CYST, FOLLOWED BY PERITONITIS RECOVERY OPERATION

I feel warranted in presenting this specimen and relating the history of this case because of its unusual

Dr Hanneage Gibbs, late of Westminster Hospital, London, has just entered upon his duties as Professor of Physiology in the Medical School of the University of Michigan

E A, et 45, married, seven children, character youngest 7 years, miscarriage two years ago, had always, until the present trouble, enjoyed good health furniture she lifted one end of a heavy chest soon after became conscious of a slight pain in the That night, however, she was awakened by n ork a sharp pain in this region, so severe as to cause her to "bend and writhe in agony" The pain extended down the left thigh and to the back, was accompanied with nausea and vomiting, and continued with great severity during the entire night before she obtained any relief whatever. On the next day her entire abdomen had become very tender and swollen (tympanitic), but the severe pain of the night before had subsided She gradually recovered from this attack, and was about again within two weeks, but she still had occasional attacks of sharp pain, and was treated for neuralgia Soon after this she noticed that her abdomen was larger than usual changed physicians and was treated for "dropsy and worms," by free purgation This greatly prostrated her and caused a return of the pain and other symptoms of the first attack

My friend, Dr O K Adams, was now called, and found the patient in great agony, the pain being most severe in the left ovarian region, but extending over the entire abdomen, which was tympanitic thighs were fleved, and her expression anxious Temperature 103° On the next day it had risen to 104° She remained very ill through the next few weeks, after which she gradually improved When the tympanitis and tenderness had subsided enough to permit an examination, Dr Adams discovered a cystic tumor in the lower abdomen, which he correctly pronounced ovarian As soon as she was able to be moved, the patient was sent to me

On examination, with the patient in the dorsal position, I found the abdomen distended by a circumscribed mass which occupied a position between the umbilicus and the pubis, projecting and about the size of the pregnant uterus about the sixth month, though not symmetrical, being to the left of the median line more than to the right. There was no resonance over the entire surface of the abdomen, even over the tumor on light percussion, deep percussion, however, gave a dull note By palpation the tumor was found to be fixed to the abdominal walls and deeply in the left pelvic region Vaginal examination showed the uterus to be retroverted, and upon it the lower surface of the abdominal tumor

To the left of the uterus a nodular mass was felt, apparently connected with the lower surface of the Movement of the tumor caused the uterus to move with it Fluctuation was elicited by bimanual palpation I advised immediate removal of the tumor, although the patient had not yet fully recovered from the last attack of peritonitis Temperature still above 100°, sometimes 101° in the aftercharacter of the inflammation, and its probable trau- blood in process of organization

sac had been suspected, although signs of pregnancy had been absent There had not been suppression of menstruation, but since her first attack of pain In December, 1886, while engaged in rearranging her ther catamenia had been very profuse, lasting from ten days to two weeks

Operation, March 15, 1887 Incision 3 inches long left ovarian region, but she continued with her usual in the usual position, and the tumor exposed. It was now found that adhesion between the cyst wall and that of the abdomen was so intimate that it was difficult to distinguish which was the cyst and which the I began by separating the tumor from peritoneum the peritoneal surface, hoping to find a place where adhesions did not exist, but in this I was disappointed, for the peritoneum was firmly glued to the anterior and lateral surface of the cyst wall, while above the intestines and omentum were closely adherent to it The tumor was now tapped, and a thin, serous-looking fluid tinged with blood, was drained away The cyst was only partly emptied, as it contained a semi-solid material which could not flow through the canula Room had, however, been gained so that the dissecsection could be continued By a careful manipulation the upper part was separated from the intestine and omentum by amputating the latter, when it was found that the lower lateral surface was adherent to the sigmoid flexion, while the base of the tumor, broad ligament and uterus were so united as to form one mass

After farther dissection the cyst was drawn out and the short thick pedicle examined This was found to contain masses of thick, clotted blood, both within and around it After further cleaning and examining, this nodular mass was found to be the Fallopian tube, distended at several points with clotted blood temporary ligature was now thrown around the base of the cyst, which was then removed This facilitated the further dissection which was necessary to form a proper pedicle, which was now transfixed and tied, and the smaller mass cut away The right ovary was healthy and was not removed The abdominal cavity was next thoroughly cleansed, a drainage tube inserted and the incision closed The patient recovered, and went home on the twenty-eighth day after the operation, but it cannot be said of her that she recovered "without a bad symptom" She did comparatively well during the first four days, but on the fifth day her temperature increased to 103°, although there was no pain or other symptoms of active inflammation, the next day it was 104° The patient now complained of pain at seat of pedicle, and the left leg was found to be slightly swollen The drainage tube was now removed, although there was still some discharge through it The bowels were also moved by a turpentine enema Her improvement after this was slow, but sure, and she sat up on the eighteenth day

Examination of the specimen after its removal showed it to be a thin-walled monocyst quite half-filled with a fibrinous material, a portion of which is presented with the cyst This was not at-This advice was based upon the recurrent tached to the cyst wall, and resembled coagulated matic origin—twisting of a pedicle or rupture of a brane of the cyst was smooth, except at several places blood vessel Rupture of an extra-uterine gestation where a dilated vein as large as a quill was apparent

icle was the Fallopian tube and broad ligament Why it was in this condition is difficult to determine, unless it was from twisting of the pedicle, but this could not be fully made out at the operation dilated condition of the veins in the cyst and in the pedicle and the evidence of hamorrhage within the cyst cavity, as well as around the pedicle, render it probable that rupture of blood-vessels from stasis had taken place

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, January 25, 1888

THE PRESIDENT, J Solis-Cohen, MD, in the

DR JAMES TYSON exhibited

FLEISCHL'S POLARIZING SACCHARIMETER,

made by Reichert, of Vienna, and explained its use The deviation is indicated by the displacement of a dark band continuous in two parallel spectra, when no glucose is interposed and the instrument reads o When a column of sugar is interposed a deflection takes place, and after the continuity is again restored the percentage of sugar is read off from the vernier Dr Tyson said the polarizing saccharimeter could not be recommended for testing qualitatively very minute quantities of sugar, say anything less than 1/2 of 1 per cent, Fehling's solution being really more Nor can it be said that there is any saving of time in testing quantitatively solutions containing less than I per cent The advantage of its use is shown in determining from day to day the quantity of glucose in specimens containing considerable amounts, where the requisite dilution and titration occupy much time In very clear urines it is not necessary, with Fleischl's instrument, to decolorize with acetate of lead solutions, but where they are not almost colorless it is necessary to treat with basic acetate of lead in the proportion of i c c to TO of urine and filter, when one tenth should be SECOND SURGEON TO THE RICHMOND, (VA.) EVE, EAR, AND THROAT INFIRMARY added to the reading of the vermer

The instrument to which DR L Wolff said Dr Tyson referred, and which I had the honor to bring before you here, is known as a polarizationmicroscope, though this is an improper term, as it is simply the utilization of the microscope stand for the adjustment of the parts of a polarizing sacchari-I imported the parts constituting this about a year ago from the manufacturer, Paul Waechter, Its principal advantage is that of price, which, to the best of my recollection, is about twenty-Like all other five dollars when bought here saccharimeters it consists of a polarizer which, as you see, is attached to the substage, on the top of this fits a plate consisting of two demidisks of quartz of opposite rotary power, which let the intersecting line be readily seen through the analyzer This latter with the vernier and homus fits into the micro-scope instead of the draw tibe The analyzer or N Howard St, Baltimore, Md, who perfected it for

The knotted irregular mass which formed the ped-scale can be so adjusted that when the nomus points to oo the two semidisks will be of an even neutral violet tint In this position it is fixed with a screw The tube is then withdrawn and the glass container with the urine is screwed in, when the whole is re-In looking through the instrument it will now be seen that the two semidisks are no longer of neutral tint, but one is red and the other blue. On rotation this inequality of color will disappear at a certain point, and when the neutral violet tints are again seen, the angle is read off. With this angle you can refer to the accompanying table and read off the amount of sugar present in grains contained in one litre, or by dividing this by ten the percent-I have used this little instruage will be arrived at ment a great many times, and find that it is quite as accurate as the larger and more expensive apparatus

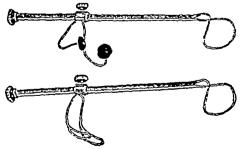

It is my custom to make about six readings, which is very rapidly accomplished, and take the mean thereof by dividing the sum of the readings by six With some practice and an eye trained for color the results come generally within $\frac{1}{10}$ of 1 per cent of the amount of sugar present. Like every other mstrument, it requires practice to get good and ac-While for those who have to make curate results many quantitative determinations of sugar in urine the polarizing saccharimeter offers great advantages I quite agree with Dr Tyson that, for single and isolated determinations, Fehling's method is quite as The general use of rapid and certain as reliable the polarizing saccharimeter together with its advantages and disadvantages, and also the preparation of the urine for that purpose, have been so fully explained by Dr Tyson, that there is nothing further for me to add

NEW INSTRUMENTS.

SELF-RETAINING PALATE RETRACTOR

BY JOSEPH A WHITE, AM, MD,

After some months of experimentation, I beg leave to submit to the profession the useful instrument represented in the accompanying cuts

The principle of its construction is so very simple, that it is strange we have not had such an appliance

Since then I have me about the middle of December used it so frequently and with such perfect satisfaction, both for the examination of the post-nasal cavity and for various operations therein, such as removal of adenoid tissue, snaring lower turbinated hypertrophies and galvano cruterizations, that I now consider it an invaluable addition to the ihinologist's For a long time back I had used armamentarium to draw the palate forward, for examination, a simple loop of silver wire, with a short rubber band which caught between the teeth when practicable, or with two long rubber loops which hooked over the ears, as less uncomfortable than passing a piece of rubber tubing through the nostrils out of the mouth, and tying it over the upper lip

The latter method I always used for operations, as more reliable and less likely to become displaced The present instrument, however. than the former does away with both methods, and is infinitely pre-

ferable to either

It is made of a square steel bar about 3 mm thick, terminating in a loop of pure silver wire heavy enough to hold the palate and light enough to be readily changed in shape by the fingers to suit each individual case, being made smaller for children and larger for a more capacious pharynx bar slides the attachment which clamps over the upper lip and holds the retractor in position sliding attachment, with two arms, requires no fixation to keep it in position, the tension being alone sufficient to make it immoveable on the square bar For greater security, however, in performing an operation, a small fixation screw is attached to the side of the slide to fasten it securely, so that facial eontortions must not displace it

As shown in the plates, I had two attachments tip made at first, one with two steel wire arms terminatin the nostrils, or on either side of the alæ of the nose, and another attachment terminating in two hard rubber buttons, which caught in the depressions a similar instrument described in the Medical Record, of Jan 14, 1881, by Dr Porcher, of Charleston

The reason of the two attachments was that I found in some cases one suited, and in others the second attachment was preferable Since the plates were made about January 1, I find the one with silver loops answers both purposes, as it can be moulded by the fingers to suit any case, just as the terminal loop of the bar which catches the palate

There is but one objection to urge against the instrument, and that is, that the bar may get in the way of operating in the right nostril, but this does not hold good if the operator is ambidextrous, and moreover, it is so small that it is not much of an ob It is applied and moved so rapidly that it can be taken away repeatedly in performing op eration to rest the patient or the surgeon perience already has demonstrated its great advantages over any known method for working in the post-nasal cavity, and I am satisfied any of my confrères who give it a trial will agree with me

A NEW ATOMIZER FOR OFFICE USE

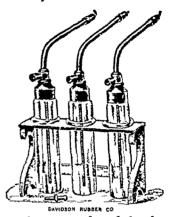

BY E FLETCHER INGALS, AM, MD,

PROFESSOR OF LARINGOLOGY, RUSH MEDICAL COLLEGE, RTC , CHICAGO

I wish to call the attention of the profession to a new atomizer for office use, that has been made at my request by the Davidson Rubber Company is known as "Davidson's Combination, No 66," by which name it can be procured through any of the instrument dealers in this city

All atomizers, thus far, have been more or less defective, but the one shown in the cut comes nearer to

perfection than any other I have seen

The spray-tube is made of hard rubber and consists of two parts, an inner and an outer The inner tube through which the fluid rises, extends from the bottom of the bottle containing the medicated liquid, to the end of the spray tube, where it is capped by a smaller movable The outer tube, which conveys the blast of air, extends from the top of the bottle, to which it is ing in silver wire loops, the ends of which caught firmly fixed by a screw thread, to the end of the instrument, where it is capped by a removable tip There are three different tips for each outer tube, which enables the physician to throw a spray either over the alveolar processes on the same principle as horizontally, at a right or oblique angle, up, down or laterally One of these tips is half an inch in length, which renders it peculiarly serviceable for throwing spray into the naso-pharynx, a place that it is impossible to reach in a majority of cases with the short tips furnished with other instruments the tips of both the outer and inner tubes can be easily removed, the tubes may be readily cleansed if they become stopped By removing the tip from the inner tube, and screwing down firmly the tip on the outer tube, this instrument will throw freely fluid cosmoline or oil, even with a low pressure, or by the hand ball

> Each of these atomizers is so constructed that it fits accurately upon the air cut off, manufactured by the same firm, and with each set is an extra attachment which enables either of the instruments to be used with the ordinary rubber hand bulb

> These instruments are put up, three in a set, in a neat little rack, and as each has three tips, the set is equivalent to nine spray tubes of the ordinary

The tubes being made of rubber, anything which

a physician is likely to employ as a spray may be used through them without injury, excepting iodine All metallic spray tubes, (excepting very expensive platinum) corrode with various solutions, and are Glass tubes are more bulky therefore soon ruined than these, are more difficult to clean, and are sub ject to a great deal of breakage, which renders them expensive, while at the same time three of them are required to answer even a part of the purpose of one of these

The spray tube itself, in these instruments, is not new, it being the same as that in Davidson's No 59, old style, hand atomizer, which, by the way, is now the best instrument in the market for the patient's use, if one is careful to order the screw top and long One of these tubes I have had in almost constant use for many years, and it is still good

I have brought this matter before the profession because I believe that we now have a much more reliable instrument than ever before, and I believe a single set of this kind would be found very valuable even to many general practitioners

For the complete outfit of a laryngologist's office nothing can surpass in utility a suitable number of these instruments, arranged in a convenient rack

The Muscular Force of Epileptics-Nature and Treatment of Granular Conjunctivitis—Antiseptic Treatment of Diphtheria—Treatment of Burns

At the last meeting of the Société de Biologie, Dr Féré read a note on the muscular force of epileptic From observations of several epileptics in his hospital ward, he ascertained that the muscular force of these patients, measured by the dynamometer, was less by one-fourth or one-third that of healthy individuals This is contrary to the gener-The author then wished to y received opinion rtain the modifications these muscular forces went in the different manifestations of the dis-Dr Féré noticed that frequently the "aura" with a diminution of the muscular force, e same was the case after the fit, whether complete or incomplete, as well as He also noticed that this enerally predominant in one of the and it was precisely in that side ns predominated This fact is at, and it confirms the theory of

nocturnal than after

Dr Féré more-

ho claims that the period of

ıplegia

e fit is comparable to an at-

conjunctivitis Starting from the principle of the contagiousness of granular conjunctivitis, which had been demonstrated by Sattler and other observers to be due to the presence of a specific microbe, the author advises the application of local and at the same time general treatment. The former is to be directed against the infecting agent, whilst the latter should have for its object the placing the organism in a state to resist this agent. As long as the granulations have not reached the period of organization, the author employs the glycerate of the sulphate of copper in the proportion of 1 to 8 parts once the cicatricial tissue is formed, the microbe becomes surrounded by a sort of fibrous shell which protects it against the action of the drug In these cases, after having rendered the conjunctiva insensible with cocaine, the granulations must be lightly touched with the point of a small camel's-hair brush dipped in a solution, very concentrated, of chromic The next day the small scar which had been formed will be found detached, and one is then able to cauterize the eyelids with the glycerate of the sulphate of copper which, in this manner, is put in contact with the microbe Five or six cauterizations with the chromic acid suffice to obtain a notable im-The cauterizations should be practiced provement At the same time the orevery four or five days ganism should be supported by means of appropriate remedies and substantial food Elevated positions are very favorable to the cure, as it has been observed that conjunctival granulations do not develop beyond a certain height

In the Archives de Laryngologie, Dr Legendre, writing on the antiseptic treatment of diphtheria, states that after having examined the different antiseptic remedies imagined against this malady, the author brings prominently to notice the energetic procedure adopted by Dr Soulez, of Romorantin, and which has been applied by Dr Gaucher, physician to the hospitals of Paris The principle of the treatment is to concentrate all the efforts of the physician in the destruction of the false membranes and the antiseptic cauterization of the subjacent mucous The treatment consists in the applicamembrane tion with a rather stiff brush impregnated with a saturated solution of carbolic acid and camphor in alcohol, but before applying the brush the superfluous liquid should be pressed out so as to prevent any of it falling into the larynx The brush is then vigorously applied to all the parts of the throat which are covered with false membranes, and in such a manner that as much of the latter may be mechani-The application cally removed as may be possible should be made three or four times in quick succession, without being deterred by the terrible sufferings This should be done twice caused by the operation daily until the false membranes have ceased to be In the intervals frequent irrigations reproduced with a solution of carbolic acid of 1 per cent should The absolute condition of the success ution of the musc lar be practiced of the treatment appears to be in the energy with One must not which the cauterization is practiced . Desormes chose only remove by rubbing the pseudo-membranous ent of granular layers, but the denuded mucous membrane must be

modified, and the penetration of infectious agents ham, Hunter, and Bichat into the capillaries, become gaping and bleeding by this denudation, should be prevented There is. however, one grave objection to this method and that is, it interferes with deglutition and alimentation by the intensity of the inflammatory reaction which Nevertheless the remedy, however it produces cruel, is necessary, and the medical man should really be armed with sufficient stoicism to be, as it were, callous to the sufferings of the patient was to the adoption of this energetic measure that Dr Gaucher attributes the saving of the life of a hospital interne (Albaram) who contracted diphthena for the second time in the same year at the hospital for children He very probably would have succumbed, judging from the increasing gravity of the symptoms, had not Dr Gaucher applied, in all its rigor, the method above described, and it was from this moment that an amelioration which ended in cure became manifest

In the Paris letter that appeared in The Journal in October last was given a new treatment for burns I now transcribe another from Le Monde de la Science, which consists in the application of compresses imbibed with a solution composed of from 5 to 15 grams of the permanganate of potash to 30 grams of The compresses are composed of calico and are frequently renewed The remedy is certainly efficacious, but only in congelations of the first or second degree, and in burns of the first degree all cases, it rapidly suppresses pain and removes inflammation When blisters are intact, suppuration is always prevented

DOMESTIC CORRESPONDENCE

BOSTON LETTER

(PROM OUR OWN CORRESPONDENT)

Dr Billings' Lectures on the History of Medicine

A series of eight very interesting popular lectures has just been delivered to the people of Boston by Dr John S Billings, of Washington, D C smaller than seemed warranted by the importance of the subject and by the reputation of the distinguished doctor, and particularly this may be said in regard to the number of professional men present From his long connection with the Library of the principle be fitted to investigate this subject, difficult on account of its ancient origin, its dependence on traditheories and beliefs concerning it among different nations and in different ages

by referring to the ten names arranged in two rows Indians on the front of the new building of the Harvard Medical School

All of them specially Then he said, in brief prominent in medicine While the lectures will be devoted mainly to indicating the influence which certain individuals have exercised on the progress of the healing art, it must be borne in mind that to fully understand this influence it is not enough to consider what physicians only have said or done. To attempt to isolate the history of medicine, and to comprehend its curious ebbs and flows of doctrine from medical writings only, is like cutting a narrow strip from the center of a piece of tapestry and speculating upon the origin and purpose of the cut threads and fragments of patterns that may be found in it Medical history includes much that belongs to the history of philosophy, jurisprudence, and science, the chief difference being the different names

The origin of medicine is to be explained from tradition and inference, rather than from history There are two classes of legends and opinions relating to this subject, the first, which we find as a tradition everywhere, is that medicine is of divine origin and thus it is that in early times we find the healing art in the hands of the priests and connected with religious ceremonies The second opinion includes such explanation as that given by Hippocrates, that it arose from experience of the effects of certain foods or injuries, developed at a later period as we shall see, into the doctrine of the empirics Among barbarous and wandering tribes, and among nations of antiquity, we usually find traces of two systems of medicine and of two classes of physicians, one lay and the other sacred, corresponding to the two legends referred to

Among the savage and barbarous nations of recent times, we find that the priests are usually physicians or medicine men, and are the superior practitioners who are resorted to in obscure or difficult cases, but also that there are others, sometimes women, who treat diseases with simple and natural remedies The essential remedies are incantations, steam baths, propitiatory offerings, music, noises, and the removal of the evil spirit by suction This may be seen from authentic accounts of the American Indian, among The whom medicine in general, refers to what is superaudiences that listened to these lectures were much natural or extraordinary, and the medicine man is one who possesses a knowledge and control of such matters, and in particular it may mean something like spirit, for every animate, and some manimate, objects are supposed to have their own medicine or Surgeon-General's office (U S Army) at Washington, physician, he is priest, rain-maker, and minister The medicine man is much more than a Dr Billings is fitted as no other man could possibly plenipotentiary of the supernatural powers, both good and evil In a report on the Oregon Indians, Major Alvord says "In some of these tribes any child may tions, its indefinite records, and the diversity of the be trained for the position of medicine man, but among the Nez Perces, the position is inherited from father to son " The medicine of other uncivilized Dr Billings commenced his first lecture in the series races is essentially the same as among the American

Among savage nations we meet with peculiar dis-The names in the upper row are eases in which only equally peculiar medicine is of Paré, Galen, Hippocrates, Celsus, Versalius, while service Among which may be mentioned the trances those in the lower row are Haller, Harvey, Syden- of the Cossack women and the peculiar fever found

in Abyssinia, which can only be cured by music and lating to Greek medicine, are found in the poems of remedy among savage tribes, not only in this country but in Africa and elsewhere, is curious and not the hands of the priests easy to explain, although it may possibly be connected with the animal instinct of licking a wound

In his "Folk Medicine," Mr Black points out that three explanations of disease and death appear to be prominent among barbarous and ignorant people, viz "I The anger of an offended external spirit 2 The supernatural power of a human enemy The displeasure of the dead"

The power of belief, faith, imagination, or expectant attention to affect the material organism is well known At the present day it is played upon among civilized people as the charm against warts by children, the faith cure and the consultation of mediums for advice etc

The moral of all this, first, that no opinion as to the causes of diseases, the effects of remedies, etc, can be made on a scientific foundation unless the Philip influence of belief and imagination has been carefully eliminated by careful and repeated experiments and observations, and second, it would seem that mental phenomena of the well and of the sick should be a subject of study by the physician, and that this should be remembered in planning a course of instruction for medical men

In the next lecture the use of magic was referred to in medicine, the remedies of the ancient priests consisting of charms, incantations, and talismans

The earliest medical book is known as the "Papyrus Ebers," which was found a few years ago between the legs of a mummy in the necropolis of Thebes Its date has been determined as 1552, B C, and it is believed to be, one of the so-called Hermetic books or writings which formed a sort of encyclopædia of science and philosophy, written by the priests It is a compilation of receipts derived from different sources salve is mentioned, and also a hair tonic and certain remedies for skin diseases are introduced Although it shows that medicine was essentially in the hands of the priests, yet it is entirely consistent with the statement of Herodotus, that in Egypt there are many physicians, some for the head, some for the eyes, and others for different parts of the body

It does not appear that medicine was regularly studied among the Jews as a separate profession until the rise of the Alexandrian schools

Among the Aryans in the earlier times, 1500, B C, the chief of the tribe or father of the family was physician as well as priest - As the Brahmins increased in power and knowledge, they assumed the sole charge of medicine and compiled the Ayur-Veda, a sacred The qualifications of the profesbook relating to it sional teacher were required to be of the highest order, and the course prescribed was to begin at the It was believed that there was a special remedy for every disease, but that its success depended upon the sanctity of the person who gave it, and that its efficiency would be impaired or destroyed if the formula of its composition were made known

as far as 3100, B C The first records we have re- of what was called the chemical school of medicine

The very general use of suction as a Homer, which we may accept as dating from about 1000, B C Then medicine was not exclusively in

In the next lecture reference was made to the fifth and sixth centuries, B C Then there were fifty to sixty temples of Æsculapius The chief ones being at Rhodes, Cyrene, Medos, and Cos, the last two

being the most important

Hippocrates (460, B C) was a native of Cos He was in the seventeenth generation a descendant of Æsculapius He was the best educated of his family, was a contempory of Socrates and Plato Physiology and pathology were not known at this time theory of medicine then was that of the four humus the phlegm, the blood, the bile, and the atrobile being produced by the brain, the heart, the liver, and the spleen, respectively

Plato expounded final causes

Aristotle (354, B C) taught Alexander, the son of He paid some attention to anatomy

Aulus Cornelius Celsus (Rome, commencement of the Christian era) wrote an encyclopædia which is the first medical treatise in Latin

The fourth lecture commenced with an account of the second Alexandrian school, which was a mixture of the religion and superstition of the Greeks, Jews, and Christians

The Arabs derived their medicine from Persia, which in turn got it from India and Greece first chemical treatise that we have worthy of the name was that of Geber, written about 840, A D

Avicenna (980-1036, A D) was the greatest of the Arabic writers on medicine, and for 500 years he rivalled Galen as an authority The greatest development of medical science was among the Moors in Spain when it was in the hands of the caliphs the rest of Europe at this time there was no progress There were more prayers and the kings and others of The eight means went to the Hebrews for science crusades (1095-1291, A D) had a strong indirect influence on medicine by producing a change in the mode of thinking

In the fourteenth century there occurred the famous "Black Death," from which one-quarter of the population of Europe lost their lives The medical faculty of Paris, in a special report, advanced the idea that it was caused by vapors from the sea Nearly all the specific fevers came from Europe The first special quarantine was introduced at Venice in 1485, A D, and it was for forty days, because the "crisis" was then supposed over

Paracelsus (1493-1541) wrote much but his writings are worthless, except in relation to chemistry and alchemy (magic) He had a tendency to personify and not to abstract, and he founded the doctrine of

signatures Van Helmont was a follower of Paracelsus who thought that the archeos, or creative principle was a ferment situated in the stomach which converted other things to be like itself

Sylvius was mentioned in the next lecture as being, Legends in regard to medicine in China, go back together with Paracelsus and Van Helmont, a founder Of the modern forms of the school of Paracelsus there remain three worth mentioning The first is mesmerism, also called magnetism and hypnotism The second modern result is homocopathy, founded by Samuel Hahnemann (born 1755) He said "There must be a perfect system of curing diseases easily, swiftly and surely But there are only three Disease must be remedied by possible methods something which produces in the healthy body either different effects or contrary effects, or similar effects But the use of things which produce different or contrary effects is the ordinary method, which is utterly bad and vicious, since it often kills but never cures Therefore the only remedy left is that which produces similar effects, and this, which is homeopathy, must be absolutely, invariably and exclusively true" The third modern result is the doctrine of Rademacher, which flourished in Germany about thirty years ago, and which taught that for every disease there is some specific remedy connected with it by the eternal nature of things

The eighteenth century, so far as medicine is concerned, can be separated from the seventeenth only At the commencement of this chronologically period there were three prominent medical teachers Stahl, Hoffmann and Boerhaave, each the founder of a system and for the time having great influence Connected with the animism of Stahl is another system of medicine, which flourished in the eighteenth century, known as the school of Montpellier, or more commonly vitalism The doctrines of Hoffmann were diametrically opposed to those of Stahl He did not believe that the soul is the cause of life, and he taught that the human body is a machine, complicated, it is true, and the life is a function of the organism Boerhaave took something from all the systems and theories, hoping to unite them all into one homogeneous comprehensive body of doctrine

The next lecture opened with a discussion of the relations of the physician to the State In ancient Egypt, Chaldea and India, medicine was kept in the hands of a particular order or caste This was also the case in Greece early, but we know that Hippocrates gave instruction for money In the so called Greek schools each master was a school for himself, teaching all that he thought requisite for the special education of a physician During the Roman Republic there is no record of any public medical in-From the tenth to the twelfth centuries stitution dates the foundation of many European hospices and hospitals Women physicians were first mentioned 1D 1057

The separation of surgery from medicine was in part due to the fact that surgery was looked upon as a handicraft, degrading to and unworthy of those belonging to the nobility, as the physicians claimed to do, and partly to the fact that the physicians were priests, who abhorred the shedding of Of the barber surgeons Ambrose Paré, who was born in 1517, acquired so great a reputation and so much influence as to give a sort of reflected respectability to his associates

Anatomy was spoken of in the next lecture

the Arabian schools, where the dissection of human bodies was contrary to religion, nor in the West, pigs being operated on chiefly, and there was no innovation in this custom until Mundinus, Professor of Anatomy at Bologna, gave demonstrations upon two human bodies in 1315 Zerbi, of Padua, was another anatomist of about the same time

Andreas Versalius (1514-1564) had the courage to controvert in some respects the opinions of Galen When men began to believe the evidence of their own eyes even if opposed to the statements of Galen and to the dictates of the church, the time had come for another great step in advance, the foundation of scientific philosophy by the discovery of the circulation of the blood by Harvey The old theory of Galen was that the veins arose from the liver and the arteries from the heart Sir William Harvey was born in 1578, and he announced his discovery in This marks the commencement of a new 1616~19 era in anatomy and physiology Closely following came the discovery of the absorbents or lymphatics, then the lacteals, and so on The practical side of medicine is typified in Thomas Sydenham, born in 1624, who is often called the English Hippocrates

Marcellus Malpighi (1661) Professor of Anatomy at Pisa and Bologna, was the true founder of minute anatomy Albert Haller (1708-1777), born at Berne, was one of the most distinguished men in the whole history of medicine He was the founder of modern physiology

John Hunter, born in 1728, was one of the most noted surgeons of his day, and formed the subject of the opening of the last lecture in the series was the founder of the school of scientific surgery His museum at the time of his death contained 131ooo specimens

Xavier Bichat (1771-1802) revolutionized physiology by introducing the study of the tissues instead of the organs as the foundation of anatomy, and of inquiry into the laws of life Charles Bell (1781-1842) was a distinguished teacher and writer at Edinburgh His works were well illustrated He gave his attention chiefly to the nervous system

François Majendie (1783-1858) was in many respects the contrast and complement of Bell shall Hall (1790-1857), at Edinburgh, was a lecturer on the principles of diagnosis and was a copious writer on medical subjects He discovered the reflex function of the spinal cord and the excito-motor system of nerves

Dr Billings concluded by saying "It is not every or any sort of knowledge that enables one to judge wisely in the selection of a medical attendant reason for this is the general ignorance of the history of the evolution of medicine into its best form of the present day-an evolution in the course of which nearly every possible mode of blundering and stray. ing from the true path has been tried over and over It is not by theories, but by long and patient again observation and experience that we come to know of the practice of medicine, and it is only the man or woman who has by long study, based on careful No preliminary education, mastered the results of all this advances or discoveries were made in this subject in work, who is to be trusted as your physician "

VICTIMS OF THE RECENT BLIZZARDS IN THE NORTHWEST ASPHYXIATED BEFORE FREEZING

Dear Sn —There is an amount of evidence and a combination of circumstances sufficient to show that the greater number of the several hundreds who lost their lives in the recent great "blizzard" of the Northwest perished from asphysia and not by freezing. Many of the bodies, when found, were in the position of grasping or clutching at their own necks or throats. In-door witnesses describe the atmosphere as having an appearance of density and darkness, similar to that stated by divers as existing when submerged with their armor in deep water. Many that escaped describe their peril as being from loss of breath or suffocation.

The terrific hurricane force of the wind, loaded with falling snow—the latter being by a fall of tem perature whose degree and suddenness has no recorded parallel converted into dry crystals, and thence by the gale ground to a fine dry ice-dustthese conditions produced a state of the atmosphere as unfit for respiration and aeration of the blood as is water for warm-blooded animal life The extent of the fatality resulting from this storm, also its horrors, will never be fully known For reasons evident and natural the papers of the region effectually suppress and underrate the actual truth Your correspondent, while just outside the belt of the storm's fatality, is sufficiently contiguous to obtain information and facts in verification of the views given. The remains of several resident victims have been returned to this localty for interment, persons absent upon business or visiting when overtaken by the storm

The Signal Service Office reported a falling barometer and severe storm at the same hour upon this memorable day, over an area whose extent far exceeds that of any upon its records From Montana to Cincinnati, Ohio, and St Paul, Minn, to St Louis, Mo, was the storm field, whose centre was stated as near Des Moines, Ia Here we have a cause for results as exceptional as itself Yours respectfully, H C MARKHAM, M D

Independence, Ia, February 8, 1888

BOOK REVIEWS.

THE RULES OF ASEPTIC AND ANTISEPTIC SURGERY A Practical Treatise for the Use of Students and the General Practitioner By ARPAD G GERSTER, M D, Professor of Surgery at the New York Polyclinic, Visiting Surgeon to the Mount Sinai Hospital and the German Hospital, New York 8vo, pp 21, 332, with 248 engravings and 3 chromo-lithographic plates New York D Appleton and Company 1888 Chicago W T Keener

"The object of this volume is a systematic, yet dish granular masses, which in time became larger, practical presentation of the Listerian principal that has revolutionized surgery within the last fifteen years" This object the author has been careful to may be regarded as the germ upon which Dr

keep in view throughout the whole book ume is not a treatise on operative surgery-and for this we thank the author-nor is it a collection of rules for the preparation and application of surgical dressings, of such works we have a sufficient quan-The book may be termed a treatise on operative surgical physiology and pathology, if there be no contradiction in this combination of words it may be said that the book is a series of illustrated sermons on the text The surgeon's act determines the fate of a fresh wound, and its infection and suppuration are due to his technical faults of omission and commission And this text is elaborated in the fullest possible manner, but without unnecessary repetition or verbiage, and without any attempt to prove what are now to be considered self evident propositions in surgical treatment. The book is not written for those that blindly cavil at Listerian principles, that would be indeed labor lost. It is full of instruction, but meagre of controversy

The primary healing of a fresh wound is now to be looked upon as a matter of course rather than as a curiosity or a piece of "good luck" Surgeons that have accepted and acted upon the great Listerian principle have now reached the solid ground of asepticism, which lies a step beyond the equally solid ground of antisepticism. And it is since they have established themselves upon the firm basis of asepticism that they have seen their scope of work widen into fields into which formerly it was dangerous to step. With this extension of the safe ground of surgery there has been a fruitful development of operative technique

We have said this much for the purpose of showing the design and scope of Dr Gerster's excellent book without copying the table of contents, and without quoting extensively from the pages of the book And if the reader will broaden his conception of the meaning of the title of the work, until the words "Aseptic and Antiseptic Surgery" imply to him all that they can possibly mean, he will have an idea of the object and scope of the work, but until he sees it he will have but a limited idea of its value. The vast majority of the illustrations are made from photographs, and convey an accurate idea of what they are intended to show. W G E

NASAL POLYPUS with Neuralgia Hay Fever, and Asthma in Relation to Ethmoiditis By Edward Woakes, MD, Surgeon to the London Throat Hospital, etc. With Illustrations 8vo, p x11, 140 Philadelphia P Blakiston, Son & Co 1887 Chicago W T Keener

This book is the outcome of a series of investigagations that the author has been at work upon for several years. Starting from the observation that in some cases of ear disease there was a catarrhal accompaniment in the nose, that the middle turbinated bone frequently became enlarged, and that the swellings gradually put forth from their surfaces reddish granular masses, which in time became larger, he noticed that these superficial granulations showed a tendency to develop into mucous polypi. This may be regarded as the germ upon which Dr Woakes has built up his theory and his book. Two years ago he published as much as then rested on what he considered a firm clinical and pathological basis, and while his views have found objectors, the facts presented have not been contravened

A useful suggestion for nasal surgeons is the blank diagram for indicating the condition of the nasal

fossæ, from anterior and posterior aspects

One cannot read this book without being impressed with the facts that the author writes from careful study and rich experience, and that if he has not unearthed the truth he has at least come nearer to it than any other writer on this subject

IRREGULARITIES OF THE TEETH AND THEIR TREAT MENT BY EUGENE S TALBOT, M D, D D S, Professor of Dental Surgery in the Woman's Medical College, Lecturer on Dental Pathology and Surgery in Rush Medical College, Chicago With 152 Illustrations 8vo, pp \(\chi -163\) 1888 Philadelphia P Blakiston, Son & Co, Chicago W T Keener

It may be safely predicted of this book that it will be very favorably received by those members of the dental profession that look upon their profession as a "science and art" and not as a mechanical trade. In the first part of the book the anatomy and physiology of the irregularities of the teeth are considered. The second part is devoted to the various means and methods of treating irregularities. The book is written in a concise style, is well printed, and profusely illustrated.

ASSOCIATION ITEMS

Programme of General Sessions of the Meeting of the American Medical Association to be held in Cincinnati May 8, 9, 10 and 11, 1888

The General Meetings will be held in the Cincinnati Music Hall and the Sectional Meetings in adjoining rooms in the same building

FIRST DAY, MAY 8, II A M

Meeting called to order by Dr W W Dawson, Chairman of the Committee of Arrangements

Prayer

Address of Welcome

Announcement of Programme of entire Session Annual Address by President A Y P Garnett, of Washington

Call for volunteer papers and their appropriate reference

New and miscellaneous business

Notification for the appointment of the Nominating Committee

SECOND DAY, MAY 9, 10 A M

Report of Committee of Arrangements Address on General Medicine, by Professor Roberts Bartholow, of Philadelphia

Annual Report of the Board of Trustees, by J M Toner, M D, Chairman Report of Special Committee on Dietetics Consideration of proposed amendments to the Constitution

Announcement of Nominating Committee

THIRD DAY, MAY 10, 10 A M

Report of Committee of Arrangements Address on General Surgery, by E M Moore, M D, of Rochester

Report of Committee on Rush Monument, by A L Gihon, M D, Chairman

Report of Treasurer, R J Dunglison, M D
Report of Librarian, C H A Kleinschmidt, M D
Report of Committee on Necrology, by J M
Toner, M D, Chairman

FOURTH DAY, MAY 11, 10 A M

Report of Committee of Arrangements Address on State Medicine, by H P Walcott, M D, of Boston

Final Report of Nominating Committee
Report of Standing Committee on Meteorological

Conditions, by N S Davis, M D, Chairman Report of Special Committee on Criminality of

Fæticide and Measures for its Prevention Report of Special Committee on Duties commonly exercised by Coroners

Reports of Secretaries of Sections New and miscellaneous business

The Sections will meet each afternoon at three A fuller programme, including a list of papers to be read at the Sections, will be published about April 7

NECROLOGY

EDWARD FLINT, M D

Dr Edward Flint died May 30, 1880, in Leicester, Mass, the place of his nativity He was descended from an honorable ancestry, the first record of the family in this country being of Hon Thomas Flint, who came from Derbyshire, Eng, to Concord, Mass, m 1638, "possessed of wealth, talents and a Christian character" From him presumably come all of the name in this region His great-grandson was Dr Edward Flint, who located in Shrewsbury, Mass, in 1756, a surgeon and physician of repute in his His son was Dr Austin Flint, who at the age of 17, was a soldier in the Revolutionary army, subsequently toward the close of the war, a surgeon stationed at or near West Point, and present at the surrender of Burgoyne He had two sons who were physicians, Joseph H and Edward, the subject of this notice The former was father of the late Dr Austin Flint, of New York

Dr Edward Fint was born in Leicester, where he lived and died at the age of 90 years and 6 months. His medical life extended over a period of more than half a century, during which time it was said of him, "that he was known to every man, woman and child around, trusted in his profession, and respected as a man to an extent rarely exceeded." He never sought public distinction, but made the

careful discharge of professional duty the chief object of life, and pursued it with conscientious fidelity, regardless of personal comfort, till compelled by the infirmities of age to relinquish

He was a life-long member of the Massachusetts Medical Society, at one time its Vice-President, and for many years one of its councillors likewise an early member of the American Medical Association, from 1848, retaining membership therewith for many years plexy, quite speedily proving fatal

almost unique, I believe, which is, that the late Dr Austin Flint, of New York, and T S Flint, of Massachusetts, make the fourth generation in successive line from the first Edward Flint, who have followed the medical profession, while the present Dr Austin Flint, of New York, is the fifth

EDWARD BARTON, M D

Edward Barton, M D, was born in Orange, Mass, Feb 5, 1803, and died at South Orange, May 7, 1880, He was the son of Pearly Barton, at the age of 74 MD, and direct descendant of Samuel Barton, of Colonial times, who in 1690 resided in Framingham, He was chiefly a self-educated man, though he attended the district school, and later the academies of New Salem and Deerfield He studied medicine with his father, and attended lectures at Pittsfield, Mass, graduating first in his class, according to the testimony of Professor Parker, at Woodstock, Vt, 1831, at 25 years of age His expenses he paid by teaching school, winters

Commencing practice at Sullivan, N H, after four Here he remained years he returned to Orange three years, when he went to South Orange intellectual capacities were of a high order, he had keen perceptive faculties, was investigating, discriminating and a hard worker His judgment was remarkably good, his convictions firm, he was honest, kind and courteous to all, the welfare of his patient was always first in his mind In consultation at the bedside, all looked with confidence to him and valued his decision

He became a member of the American Medical Association in 1858, and attended meetings in 1860, 1863 and 1865 Since 1841 he was a member of the Massachusetts Medical Society, and since 1852, a member of the Franklin County Society, holding office in each, was President of the latter Society in 1860 and 1861, was honorary member of the Worcester North Medical Society and was one of the founders and the first President of the Miller's River Medical Society

MISCELLANEOUS.

COOK COUNTY HOSPITAL, CHICAGO PUBLIC EXAMINATION TO FILL VACANCIES IN HOUSE STAFF

Notice is pereby given that a competitive examination will be reld at this institution March I and

2, 1888, for the purpose of selecting eight physicians to act as Hospital Internes

The examinations will be in writing and upon the following subjects (1) Anatomy, (2) Physiology, (3) Materia Medica and Therapeutics, (4) Chemistry, (5) Practice of Medicine, (6) Surgery, (7) Obstetrics and Gynæcology, (8) Pathology, (9) Ophthalmology and Otology

By resolution of the Executive Committee of the His death resulted from apo- Medical Board, candidates must be graduates of a regular medical school recognized by the Illinois There is one fact in the history of this former State Board of Health or within four (4) months of graduation from such a school

Denslow Lewis, M D, Secretary of the Medical Board

NEW YORK STATE MEDICAL ASSOCIATION—Fifth District Branch -The next meeting of the Fifth District Branch will be the fourth annual meeting to be held in Brooklyn, on Tuesday, May 22, 1888 There will be a morning and an afternoon session All Fellows are solicited to contribute to the meeting, either by reading papers, notes or communications, or by exhibiting specimens All papers offered are the property of the Branch, and will be published in a current medical journal The Secretary desires to be notified of the title of any paper to be offered as early as convenient

E H SQUIBB, M D , Secretary P O Box 94, Brooklyn

Professor Asa Gray, the distinguished botanist of Harvard, and one of the best known scientists in this country, died on January 30, at his residence in Cambridge, Mass, at the age of 78 years Dr Gray was a graduate in medicine, but after a very short experience in medical work entered upon the study of botany and became, perhaps, the most distinguished of Ameri can botanists

ADDRESS

THE IMPORTANCE AND ERADICATION OF SYPHILIS

Delivered before the Rocky Mountain Medical Association, June 5, 1887

> BY HORATIO R STORER, MD, OF NEWFORT R 1, PRESIDENT OF THE ASSOCIATION

LADIES AND GENTLEMEN OF THE ROCKY MOUNTAIN MEDICAL ASSOCIATION

In accepting the honor that you so kindly conferred upon me at St Louis, the Presidency of our Association for the present year, I had hoped that I should be able to attend the Chicago meeting, for I appreciate your courtesy and fully share in your desire that the annual convocations of those who crossed the continent together in 1871, should increase in interest the nearer we approach that final passage into an unknown country that is before us all, and from which there is no return

It seems to me that the older we become, self limited as is our organization, and by its constitution unable like almost all other societies to take into itself any new or younger life, the more incumbent it is upon us to appreciate that each year our circle, already so limited through the decease of valued associates, contracts still closer upon itself, and thereby we are pressed into a more intimate companionship with each other, a nearer touch Besides this, increased sense of mutual sympathy and support that we possess as the effect of the tie of close corporationship, which is to be broken only by the decease of the last survivor of our number, that there are duties, correlative to the occasion that first united us, and as peculiar responsibilities to be measured only by the opportunities of exerting a deep public influence, that are yearly our own through our connection with the American Medical Association, as an integral part of its history

The trip to California, pleasureable and health giving though it was to all of us, was undertaken for a more serious reason, and produced a weighty To many of us it was attended by much inconvenience and to all no slight expense, in both respects fully equalling indeed a summer's trip to The journey was in truth a mission, to

Association to a portion of the country that, rich as it might be in natural wealth, was yet in the regard referred to, virtually a professional wilderness Practitioners there were there in abundance, graduates from the chief schools abroad as well as from our own, and already they had rival medical colleges and even journals But as a whole, the physicians of the Western Coast were dissociated from each other. personal feuds were intense, empiricism was aggressive, and associative efforts for the common welfare were as yet limited, if not almost unthought of The City and County Hospital of San Francisco was already known as affording remarkable facilities for studying affections depending upon the peculiar physical characteristics of the State and its still more novel mercantile and social as well as climatic phenomena Mountain fever was to be found in its wards, no less than all the major aneurisms, while at the Insane Asylum at Stockton, which I visited with Dr Scott, of San Francisco, there existed under Dr Shurtleff's wise classification, an abundance of, to us of the East, unusual mental aberrancies There was at once a fertile field for our study, and a rich realm for us to assist in bringing within the influence of the National Association

The hearty reception that we received from our professional brethren, the cordial welcome from State and civic authorities, and from all the people to their private homes, is still as fresh in our minds as though it were but yesterday, and we are all conscious that while as a body the American Medical if more perfect union should give greater strength, Association left its impress for good upon the State to each as to all, we ought, I think, to feel with the of California, we ourselves without exception became subject to influences which not only freshened our spirits and expanded our ideas, but opened our very selves to ways of thinking, to aspirations, charitable judgments, and tender and affectionate relations with that people of the far West, which we shall all carry with us, enduring and undimmed, throughout our

Most intimate, however, of the ties that we then formed, warmest in sympathy and fraternal interest, because shared in by each and every one, is that of the members of our circle with one another joys of each there should be a general participation, in the sorrows of each a common grief Greater still is the influence felt when an occurrence of importance affects us collectively and as a whole It is, therefore, with heartfelt emotion that I have to announce to you the recent decease of our most venerable assoconvey the influence and authority of the National ciate, our patriarch, Dr John Wadhams Russell, of

Mt Vernon, Ohio, who died on March 22, 1887, in read a paper upon some matter within its scope, at his eighty-third year, at his home

Dr Russell was a successful practitioner, especially as a surgeon, and was noted for his skill in removing vesical calculus Indeed it was said of him by our biographer, Dr Toner, that "he had performed as many, if not more, capital operations than any inland town surgeon in Ohio "Repeatedly offered a college chair, he preferred the less prominent but no less responsible duties of private life He had studied his profession in South Carolina, at Yale College, the Berkshire Medical College, and at the Jefferson, in Philadelphia He was, therefore, nullius addictus jurare in verba magistri, but from having been taught by numerous instructors, he had received a broader impress He was a member of the Medical Society of Knox County, Ohio, of the State Medical Society, since its organization, and its President He had been President of our own Association during its eleventh year, 1881-2, and delivered the Anniversary Address at St Paul He had also acted as President at the annual meeting of the previous year, at Richmond At the meeting of 1883, at Cleveland, he is recorded as having made very impressive remarks, during which "as the most aged member of the Association, he dwelt upon the uncertainty of life, and the possibility of his soon being called away from his labors, and he admonished all to be ready for the great summons" which he has now, full of years and of honors, himself in person answered brief but feeling notice of the deceased was given by our Ex-President Davis, in The Journal of the AMERICAN MEDICAL ASSOCIATION, for April 2 last

(page 381), and in the same journal for April 9, there

were printed the obituary resolutions of the Knox

County Medical Society, concerning their late mem-

sketches of Dr Russell will be found, by Dr Wm B

Atkinson, Permanent Secretary of the American

Medical Association, in his volume upon the Phy-

sicians and Surgeons of the United States, Philadel-

phia, 1878, p 242, and by our colleague, Dr Toner, in his work upon the history of our own Association,

pages 346 to 349 A good man has fallen We shall

Interesting biographical

ever cherish his memory May he rest in peace In seriously deliberating what I should speak to you of upon the present occasion, it was clear that my topic, however I might select it, should be at liver it an address upon "Female Hygiene" This least connected with our Rocky Mountain pilgrimage It was as evident also to me that my subject should be of equal importance with our then mission, and though to offer you such, instead of mere reminiscences of our pleasant travel together, but increases the difficulties of my task, I have felt that in your behalf I had no right to evade the responsibility, lose the opportunity, or make light of the important duty, each of which considerations, as I have already said, is at our annually decreasing gatherings peculiarly incumbent upon the members of the Rocky Mountain Medical Association

mined in my mind, I received from Dr Rohé, Chairman of the Section on State Medicine, of the American Medical Association, the request that I would "equally to the married and unmarried, and so gen-

the Chicago meeting, and though I replied that to do so in the usual manner was impossible, so completely was my time occupied by the preparation of a paper for Dr Bell's Santarian, upon the "Medals, Jetons and Tokens illustrative of Sanitation," a second chapter of the series that I began by the "Medals of Obstetrics and Gynæcology," published in November and December last in the New England Medical Monthly, as a part of my proposed work on the "Medallic History of Medicine," Dr Rohe's letter has yet settled my decision regarding the topic I Old men and aging women, should present to you as are we doctors and doctors' wives of this Association, have a valid right to give counsel It is for our children in the profession to carry our views into practice The higher and more universal our theme. the greater its claim upon their attention and assis-

In asking your attention, therefore, to a brief statement of the permanent importance and progressive eradication of that bodily disease, by common consent acknowledged as the worst of all, I am recognizing the constantly increasing tendency of our profession towards preventing both public and private pestilence, which for a thousand reasons is so much better than permitting their foothold and then in vain, per-In what I shall say, I am haps, attempting a cure virtually still further developing a paper that I read to the American Medical Association in 1878, and was published in its transactions, and I am securing your cooperation in a movement for the protection of Society from injury as fatal to its health and indeed its existence, as it is destructive to its morals You will find, I trust, that repulsive as is the subject, it is yet one that can legitimately be brought before a refined circle like that of even our own lady members without any violation of propriety, and be quite sure to awaken them to take part in the preservative crusade to which Gross, Marion Sims and Gihon have given so great vitality

That my choice of subject is singularly appropriate for your consideration will be evident for still another In addition to the motives that we had in reason common for our transcontinental journey, in my own instance there was still another I had been invited by the State Board of Health, of California, to dewas given, and perhaps attended by some of those now present, at the State House, in Sacramento, on April 28, 1871, and repeated, by request of the physicians of San Francisco, in the latter city upon May 25 In the course of that lecture, which was published in the First Biennial Report of the California State Board of Health (1871, appendix, pages 1 to 17), I alluded with some warmth to a statement that had appeared in the Transactions of the Third Session of the Medical Society of California It ran as follows "In no place of civilization do the causes (of ill health edical Association

While the subject of this address was still undeterin California." These causes, it was claimed, were This applies," it was further stated,

chiefly "the yielding to the seductive allurements of dissipation

eral is it that I believe," said the writer quoted, "that if we consider what is seen in the naval and mercan-I am correct, when I estimate two in every three females (in California) who have reached 15, to be victims of this dissipation" (Loc cit, 1858, p 133)

In reading this statement, and in carefully re-reading it, it seemed to me that it could mean but one thing, and such was the impression of others whom I I therefore stated in my address at Sacramento that I thought that though the remark referred to had been written by a gentleman who lived upon the spot, it must in the very nature of things have been unintentionally greatly exaggerated referring to the matter at all gave rise to extremely great offense, and I was bitterly criticised by the radically misunderstanding their drift Though it seemed to me at the time that in neither of these respects could I have been in error, I yet cordially regret at the expiration of nearly twenty years that I wounded our friend's feelings without intention, and frankly admit that had I then known what was afterwards claimed, that the apparently very plain and direct language of his paper referred only to the late hours, the dancing parties, and if within bounds innocent amusements which we do not always hesitate ourselves to permit to the young people of our families, I should have refrained from comment writer of whom I have spoken holds deservedly high rank in our profession both at home and abroad as a gynæcologist, and I am sorry that I was ever the means by so carelessly touching the self-inserted thorn, of causing him a moment's torture

As a fitting sequence to what I have now said, I may mention that remaining in California long after most of our companions had returned to the East, no less time indeed than until the following October, I had abundant opportunity of studying the question that had thus early presented itself to me admitted professionally into the families of many of the men of 1848 and 1849, which would have been the most likely of all to have suffered in the way indicated, I visited with the late Dr Logan, of Sacramento, at that time Secretary of the State Board of Health, and subsequently President of the American Medical Association, the Chinese bagnios of San Francisco, at the request of the Governor of the State, and made careful inspection of their inmates, and I had abundant opportunities of observing the private cliniques as well as hospital practice of my medical friends, and I was as astonished at the general good health of the people as regards specific hereditary infection, as I had been when visiting the Chinese quarter, at the vital tolerance shown by the opium drunkards

In nothing is the conservative force of Nature, in protecting the race as a whole, evinced more clearly than in her way of eliminating constitutional taints and impurities, alike by precipitating them downwards into the grave, and upon the other hand by throwing them off as froth thro' intermarriage with a healthier strain Were it not for this, the race would by this time have be-

tile marine of this and other countries claim that there are hardly ten seamen in one hundred who earlier or later in life have not exposed themselves to specific disease A very large proportion become affected, and yet, thanks to their good constitutions and good treatment (though often with no treatment at all, or even the very worst), how very few, comparatively, of sailors' wives and children are found constitutionally diseased The evidence of specialists in specific disease, and of dermatologists, all goes to show that there is a terrific leaven of the kind at work in every community They, of necessity, can take but a pessimistic view as to the future Face to writer in question for transferring his assertions from face with the sources of infection, presented to them the oblivion of a strictly professional annual, and for from distant localities, for such cases naturally consult a physician as far away as may be possible from their own places of residence, syphilographers may well declare the human race but one foul sink us hope that the gloomy anticipations of its possibly becoming such, may never be realized

Equally, however, do many of those who take a more comprehensive, because more distant view of this endemic plague of civilization, agree with the observers who study the body politic as though really with the microscope One can hardly take up a medical journal at random without being confronted with this spectre that will not be allayed Most forcibly is the whole question presented in a very recent number of the Sanitarian, by Dr C E Beardsley (Loc cit March, 1887, p 205), and as an immediate result, we find his State (Ohio) Sanitary Association unanimously recommending the passage of a law that syphilis should be made a legal bar to marriage

(Ibid, p 280)

In my own paper upon "The Frequently Gynæcological Origin of Inherited Forms of Strumous Disease," to which I have alluded as having been read before the American Medical Association in 1878, I drew attention to five points relative to the main question, four of which are of a general bearing, but the fifth strictly gynæcological These conclusions, then for the first time apparently so plainly stated, have not been challenged

They are as follows

1 Syphilis, like other toxemias, is more proven to become constitutional in a strumous than in a perfectly healthy subject

2 Struma, the result of syphilis, especially if from inheritance, though confessedly not uncommon, is comparatively seldom recognized as such during life, and still more unfrequently does it receive appropriate treatment

3 Syphilitic struma, personal or by heredity, is in no sense self-limited

4. The predisposition to syphilis by heredity (a very different thing from its inheritance), is both of itself and as affected by strumous and other antecedent dyscrasia, much more frequent and intense than is generally supposed

5 The transference of primary syphilis being sometimes made by perfectly healthy women who are come so generally impaired as to be corrupt, physically, themselves entirely free from specific disease, this is through and through, but we may well take comfort an element not to be overlooked in the discussion of syphilitic struma, as it bears vitally upon the questions, who are most prone to receive infection, how the virus is propagated, and in what way to attempt to restrain the spread of venereal disease

more than thus indicate the very practical directions forma in which, following these suggestions, both sanitarians and therapeutists may successfully move me to say, however, that while I am writing, corroborative evidence of their importance has been furnished by Dr Wm Henry Porter in an article in the N Y Medical Record, summarized in the St Louis Medical and Surgical Journal for April 1887 Dr Porter discusses the "Etiological Significance of Syphilis as a Factor of Disease in connection with Pulmonary Lesions," and among his conclusions are these The pulmonary lesions attributable to syphilis are quite common, more so, however, in females than males The disease is as frequently inherited as acquired The lesion is most often at the apex, and generally that I may get suggestions that will aid me in the involves both lungs Cavities are found, and the future changes are phthisical in so far that there exists progressive consolidation, followed by softening and the cold and extreme heat of Dakota, is liable to many formation of cavities The ultimate results of a case depend a great deal upon early recognition, before grave organic lesions have occurred

There is reason, as I have said, to believe that the strumous diathesis renders the development of syphilitic phthisis, through direct or inherited infection, more likely to be determined There is equal reason for the supposition that the occurrence of this latter will intensify the strumous taint—or at least evidence is as yet lacking that such is not the case ever direction this may be at last determined, my own deductions will still prove true, namely

I That the more completely we prevent (by wise sanitation), control (by intelligent supervision), and perhaps cure (in certain cases by specific treatment), phthisis and other forms of strumous disease, to such an extent do we limit the probable infectious propagation and intensity of syphilis

2 Similarly, the more actively we endeavor, by public and private measures other than those now indicated, to absolutely eradicate syphilis from any community, to such an extent do we limit the occurence, personal and by inheritance, of the various forms of strumous disease.

3 A fortiori, and even to a greater extent than has as yet been or can be effected by governmental or private attempts to control venereal disease by examining for or treating its primary lesions, by thus removing from our midst a large moiety of the material upon which the disease has thus far subsisted, we may hope eventually to get it under control

What I have now said, and the many practical thoughts to which it cannot fail to give rise in your minds, will be considered, I trust, to suffice for the present occasion Brevity is universally conceded to be the soul of wit without tiring you, I have indicated a direction in and not infrequently at the base which, whenever occasion may permit, you may con- itant râles are distinctly heard scientiously throw your whole influence towards aid- tough mucous character, and often frequent and coing the suppression of the fearful malady which per-pious hæmorrhages are present vades the community under the least suspected a case in which there was any evidence or history of

guises, and in quarters where its existence would never for a moment be imagined

My task completed, I have to wish health, long life and happiness to you all, and many future pleasant I shall not at this time and in this presence do reunions, perhaps some day even once more in Cali-

MEDICAL WORK AMONG THE SIOUX INDIANS

Read before the Dearborn County (Indiana) Medical Society, September 25, 1887

> BY FREDERICK TREON, MD, PHYSICIAN TO CROW CREEK AGENCY

I desire to give a brief outline of my work and experience among the Indians during the past year, hoping it may prove of interest to the profession, and

The Indian, from constant exposure to the severe diseases, often sleeping, when the mercury registers 40° below zero, on the cold ground with only a thin tipi for shelter and a dirty blanket to wrap up in, while during the summer, when the temperature reaches the extreme height of 120° F in the shade, he exists upon the commonest food, often gorging himself with the native buffalo berries, plums, and choke cherries, and drinking the vilest water imagin-

Consumption and Scrofula — The first diseases to which my attention was directed, when I reached the Agency, were consumption and scrofula the cases treated 87 have been of consumption and 30 of scrofula Out of 57 deaths, 40 were from consumption, 4 from scrofula, and only 9 from other diseases, while 4 were accidental Thus it will be seen that about 7 out of every 10 are dying from consump-In my experience it has been the exception to find among the Crow Creek Indians—who are of the great Sloux tribe, and known as the Yanktonia Sloux -a good healthy subject I find, basing my belief on the death-rate for the past year, that in less than another century this particular band of Indians will be extinct, and so far as they are concerned the great Indian problem will have been solved

Consumption among these people appears, in the adults, always to follow an acute attack of bronchitis or catarrhal pneumonia, while usually the first symptom to which your attention is called in the child is a looseness of the bowels amounting at times to dys-The child grows weak, becomes emaciated, entery and often refuses food, while at other times it pos-At first the mesensesses a most ravenous appetite tery alone appears to be affected, but later on a cough sets in, dulness on percussion is perceptible I shall have done my duty if over one and sometimes over both lungs, at the apex Mucous and crep-Expectoration of a I have yet to find

I have never seen them have a chill symptoms I have described are not always present The patient sinks rapidly and dies from asthenia While the Indian is a patient sufferer, and possesses unlimited courage and fortitude, yet he dies very suddenly and when you least expect it

phthisis pulmonalis I do not consider my experience sufficient to warrant me in saying this will not happen, but my observation for the year supports the

Syphilis and Gonori haa —That these people are inoculated with some specific poison one cannot question, a disease that is hereditary and may have had its origin in syphilis, and yet I have my first case of an acute attack of that disease or of gonorrhœa to see among them-a most noteworthy fact

Pneumonia —During the spring of the year these people have a great deal of pneumonia and the mortality is heavy It is not an uncommon thing to see the women, when winter is breaking, sitting in the

water or rolling in the melting snow

form, and often of a violent type, not infrequently terminating in ulceration and opacity of the cornea I have had as many as 50 cases under treatment at From the tainted condition of their blood the disease is often obstinate and difficult to manage I have a case under treatment now, in which a girl, Maggie Moccasin, was sent home from the Wabash School, in Indiana, as incurable and hopelessly blind The child aroused my sympathy from the fact that she was, aside from being a very bright child, able to speak very good English I found her in a miserable, dirty hut, unable to cross the floor unless led I tried to get her into the school so that I could treat her, and to this I obtained the Agent's consent, but there were were a great many objections to this and the idea had to be abandoned At last I found a helper in the Rev Mr Burt, the Episcopal missionary, who, with his good wife, took her into their home and provided the child with every comfort and attention possible She had complete opacity, with slight of the cornea At first I thought I should perform iridectomy and make an artificial pupil for the left eye, but concluded to try treating the eyes, first with a 4 per cent solution of atropia, and later with the yellow oxide of mercury ointment, giving her at the same time full doses of the syrup of iodide of iron I can say that the results from the long and patient save the limb only has the right eye cleared up, but the left has also been very much reheved and greatly improved The child now sees to thread a needle and is beginning to read

From the long severe winters I have seen a great many frost bites I have seen any number of them with their cheeks frosted, and have treated a great many cases of frozen feet and hands

very peculiar and annoying ulcer that is very common among these people, and that I have never seen anywhere else The first symptom is a severe pain, usually located upon the extremities, a circumscribed pain over a spot not larger than a nickel This lasts for about forty-eight hours, when you can feel very I have noticed that patients that have enlarged distinctly a small hard substance like a shot, deep glands and scrofulous sores do not, as a rule, have down in the tissues, very similar to that found in About the third day there is a slight flush small pox on the surface, then a small blister appears, which is always superficial, on the second or third day after the blister appears it breaks down, and a number of others appear in the same locality A thin sanguineous fluid is discharged, and the blisters consolidate and form one large but superficial ulcer After a few days resolution commences, healing over without leaving a cicatrix One person may have these for a long time, when one crop heals, another appears I have met with the best results in the treatment of this trouble by using an ointment made of the oil of cod, with an alterative given internally

Schools — The schools of Crow Creek and Winnebago Reservations are now in full operation, with Eye Diseases—Conjunctivitis appears among the good sanitary surroundings. We have a boarding-Indians in the spring and autumn in an epidemic school at the Agency, a Catholic Mission 18 miles northwest, just completed at a cost of \$20,000, and Miss Grace Howard's Mission, now nearing completion, is located twelve miles southeast from the Agency This school is under the Episcopal Church, but erected by Miss Howard It will be for returned Hampton pupils These schools will accommodate The Indian child does not learn about 400 children so rapidly, as a rule, as does the white child, but surely a good work is being accomplished, a work that will tend more to civilize these roaming, restless people in the future than any other one thing work in the schools has been the most successful, there the patients are directly under the care of the whites, and directions are carried out to the letter, but it is in the schools that I have found diseases in

their epidemic forms

Surgery —I have not found a great deal of surgery to do, but desire to mention one or two cases that have interested me One was a case in which a young Indian driving a reaper stopped to fasten up staphyloma of the left eye, while the right eye had the trace of his inside pony. He neglected to throw almost a complete opacity, yet there was no bulging his machine out of gear and, the flies being bad, the ponies started, he was caught in the sickle and his right leg nearly severed at the junction of the lower and the middle third, the fibula and tibia were both badly cut and mangled At first I thought that nothing short of an amputation would save him, but concluded to be conservative and make an effort to I had to treat him in a tipi on a bed use of these remedies have been most gratifying, not made on the ground, this, however, was not a disadvantage, as it afforded him good hygiene I made for him a rather ingenious arrangement in the shape of a camp stool for the limb to rest in This allowed of a free circulation of air under the injured member, gave excellent drainage, and at the same time made an admirable cushion I used simply a wash of carbolic acid, and kept the limb in good position by means of side splints I visited him often to see Ulcerous Affections -I next desire to mention a that the wound was kept clean and to look after his

condition generally I removed a number of small never see one so bad as this spiculæ of bone, but the wound healed kindly and more of a large fish than of a human being bony union took place by a provisional callus After nine weeks of confinement I put on a brace and have with lice, both head and body I have not infrehim on crutches I predict for him a fair limb and I am gratified with the results

Malignant Disease -I have met with but one malignant or cancerous tumor, and that was in a halfbreed at Lower Brulé He was under the charge of Dr J B Graham, the Agency physician at raw meat they have enormous tapeworms, as well as that post The disease was located upon the right lumbricoids and ascarides shoulder and neck We operated upon the patient a few weeks ago The doctor first destroyed what retain their native "medicine men," who are the he could of the growth with chloride of zinc and most remarkable frauds imaginable. They treat their other caustics of an anæsthetic, using the A C E mixture, after and singing or chanting a most dismal song, which is which we cut away all we could with scissors we scraped out the extensions with a sharp curette, Sometimes, however, they do administer remedies after which we used the thermo-cautery at a white I remember a case of conjunctivitis that fell into the heat, cauterizing the entire surface. After this Dr hands of a "medicine man," who treated the eye by Graham used a dressing of chloride and oxide of putting brass filings into it. You can easily guess the

in general health

skin, with a very smooth surface and soft texture, which, from a lack of cleanliness, with their tainted condition, renders them highly susceptible to skin and ichthyosis are often found among them after I arrived at the Agency I was called to see tain diseases, or a certain herb will cure when admin-"Skunk Robe," an Indian who was suffering with istered by him Then the man gets up and, with a He told me he had been afflicted for some time He was covered in places with scales, localized on flag, red or yellow, which is to communicate with the the lower extremities and breast He was quite old | Great Spirit, the sun or the moon, and is the fulfilling and a very devout Christian I gave him internally of a promise made by the "doctor" to the Great cod-liver oil and, contrary to the advice of some au- Spirit, for which he is to receive in return the restorthors, Fowler's solution tar ointment and instructed him to keep clean and He went to his home on Crow Creek, about seventeen miles from the Agency, to which I frequently drove to see him On my first visit to his home I found the disease very greatly aggravated and every imaginable space on his body covered with a dry, haish, non-perspiratory, scaly, ill-nourished skin, showing the dark peculiar caking upon it so diagnostic of his trouble Even the soles of his feet, as well as the crown of his head, were a mass of huge them gets very sick they have a medicine feast, and I found him in a miserable old hut, dirty and illy ventilated, lying upon a cot too utterly dirty and filthy to describe I learned that he had been in the habit of going out naked and rolling and bathing in To me the case was a most remarkthe cold snow able and interesting one, and I made that long drive a number of times to see him I believe that if I could have succeeded in tiding him over until spring I might have, with the aid of a well ventilated tipi and the pure fresh air, at least afforded him some relief, but a new complication, in the nature of an acute it again, no matter how good it is I recall three attack of bronchitis, set in, due, no doubt, to the snow instances in which this happened. They usually bury hather and he does not be the snow instances in which this happened. bath, and he died I have to regret that I could not their dead in the ground, though some of them are have brought him, with so rare a disease in such an placed on poles or in the trees, while others are set aggravated form, before you, for you will doubtless on the hills Where a coffin is used they come for

He reminded one

Parasites - These people are constantly loaded quently seen the women "lousing" one another and eating the vermin Once I saw a group of dirty squaws sitting on the ground and, as there were not enough to supply all, a shaggy dog was being gone over by one of them As they eat a great deal of

Medicine Men - These Indians, to an extent, still We placed him under the influence patients by "pow-wowing" and drumming over them Then a deep guttural sound and hideous in the extreme I am informed that the wound has healed results. I have been told one of the ways by which very kindly, and the patient is very much improved they gain their knowledge and become "medicine men" They go on the hill-tops, and in the extreme Skin Diseases —The Indian has a very delicate heat he with their faces to the ground for days, and refuse food or drink, until from exhaustion they become delirious, then it is, they claim, that a spirit comes to them in the shape of a wild animal, or some-Itch is very common, and eczema, herpes times it is a weed that speaks to them and sings them Shortly a song, telling them that the song will drive out cer-I found him in a tipi in the grove near drum, is a full-fledged doctor. You can always tell when they are at work, for they run up a medicine Locally I had him use a ation of the patient The Indian believes that all diseases are the result of certain power delegated only to the medicine man They think that consumption is produced by blowing into the system a seed of grass, and that he alone has power to heal them They attribute headache to an evil spirit, and nothing but the drum and "pow-wow" will drive the spirit away They believe, however, that a boil is the result of a silent shot from a duck, while a car-When one of buncle is from the shot of a goose make medicine over the patient I once attended a feast of this kind The soup is made of dog, which, by the way, is considered a great luxury They all eat while the "medicine man" beats a drum and sings or chants a most fearful and dismal ode, which is kept up for hours or until the soup is exhausted

The Indians, as you may well suppose, are very superstitious, and if they can avoid it they never allow the patient to die in the house or tipi happens they tear down the house, and never live in

it before the patient dies and, if possible, put them into it and carry them out of doors to breathe their last

A very amusing incident occurred at the Agency some time ago A squaw made complaint against her liege lord—who, by the way, was a "medicine man," and said he was not providing for her made a bold speech in his own defense, in which he said, with great pomposity "I am better than other men, why? Because I am a doctor I have pomes and cattle, why? Because I am a doctor My body is worth gold, why? Because I am a doctor

Not long since one of these medicine men called on me to prescribe for his son for retention of urine I did so, and the boy soon recovered I was not aware at the time that the fellow was a "medicine man," but one day he came to me and said friend, my heart is very good, your medicine is good, my boy is well" I said, "How?" He then laid his hand on my arm and said he was a doctor and that I was a doctor, and we should be friends He then shook my hand and went away

But notwithstanding these people to some extent retain their medicine men, yet they appear to be progressing, and many of them have come to know that the white man's medicine is far superior to the mystifying, conjuring pow-wow of the Indian, and they are fast learning that the Indian doctor is a fraud am indeed encouraged and gratified with my work and the results One very annoying thing, however, is that they have no idea of our plan of reckoning time, and medicine can only be given at intervals of about six hours, or three times a day, so that the physician must be exceedingly careful in what doses he prescribes and what he gives, for the Indian is hable to drink the contents of a bottle at one time

But these people are surely progressing we stop to consider that only a dozen years ago they were a wild, savage race, huddled together in one large band, living in tipis along the Missouri, without mellitus or Bright's disease is the sequela an Indian house on the Reservation, and all in blankets, and that to day nearly every one of them have their lands in allotment and are living in good comfortable houses, while many of them are clothed in citizens' dress, and are farming and getting for themselves herds of cattle and horses, we can but say that they have made a marvelous and rapid advance towards civilization, and I predict that the day is not far distant when they will be self-sustaining With the aid of the efficient force of employes and the energetic missionaries at work, we hope for great achievements in the future

Summary - Cases treated in all, 790, patients visited in homes, 97, in tipis, 100 I have traveled to see sick on horseback 94 miles, have walked 97 miles, have traveled in spring wagon 1,170 miles Births during the year, 55, deaths, 57

THE USE OF WATER IN THE TREATMENT OF RENAL AND HEPATIC DISEASES

Read before the Northwestern Medical Society, January 10, 1888

> BY E F ELDRIDGE, M D, OF NEW LONDON, WIS

For the past five or six years I have been much interested in the cause, pathology and treatment of the various morbid conditions of the kidneys, more particularly in that departure from the normal that is quite frequently met with in this country, especially among business and professional men, which is the direct result of the ingestion of too great quantities of carbo hydrates in the form of fat, sugar or starch, over-stimulation of the nervous system with alcoholic beverages, the immoderate use of tobacco, excessive mental activity, worry, lack of sleep, dissipation, etc. The frequency with which our attention is called to this condition and the subsequent history of these cases, if left to themselves, is such that it should excite our deepest sympathy, and receive our most earnest attention

In these cases irritation and congestion (which finally become chronic) of the kidney are induced by the continued excretion of uric acid, the results of imperfect digestion or oxidation of albuminoids, the straining off of large quantities of partly converted starch in the form of sugar, or of an excessive amount of the different combinations of the phosphates from the destruction of nerve tissue Tobacco and alcohol produce the same results, the former by paralyzing the coats of the arteries, and the latter by increasing the heart's action and raising The result of either is to dilate the blood pressure the capillaries to twice their original calibre, and produce a condition of static congestion and functional incapacity If this condition is allowed to continue, organic lesion is the result, and either diabetes

In prescribing for these patients it is necessary to ascertain which of the above causes is the active one in the particular case under consideration, and remove it if possible, if not, as is often the case with worry, overwork, etc , to modify its influence by the aid of proper food, hygienic surroundings and suitable remedies, so as to reduce its injurious effects to a minimum

The great struggle going on at the present day among professional and business men for the leading position in their respective callings is the result of a firm belief in the doctrine "that the survival of the fittest is the inevitable" In regard to health and life this is not true, and should be so understood by patients suffering from any of these maladies Errors of diet and deportment must, of course, be corrected

The second consideration is that of the removal of the waste material, or of getting rid of the "accumulated surplus" with which the system is loaded, and which is continually undergoing a retrograde metamorphosis, the result of which is the production of highly poisonous irritants in the form of uric acid, etc In no way can this be accomplished (so far as I know) as rapidly as by solution or hydration, in fact, this is the only way with which I am acquainted, and drink freely of pure water, i e, that which conthat solids in this form can be removed from the tains the smallest amount of solids, and of course no

In looking for a solvent for these substances, I find none that can approach the capacity of water, the greatest solvent known, and, reasoning from the laws of chemistry, and the actual results of experiments, those waters that contain the smallest amount of salts, are capable of dissolving and holding in solution the greatest quantity of solids, and particularly those represented by combinations of lime, uric

I am thoroughly convinced that any and all waters that are in fact what they purport to be, t e, waters containing an unusual amount of mineral substances, are far inferior to those that are comparatively free from salts of all kinds

While in practice in Boston I was in the habit of prescribing in these cases "Commonwealth Water" from the famous spring of that name situated near Waltham, Mass, that is a very pure water containing about 35 grains of solid ingredients to the gallon I found this superior to any of the much vaunted waters of a higher specifice gravity, for the simple reason that it was not already saturated or loaded its source, the different strata of sand through which with solids in solution

city, New London, Wisconsin, and the following season, after assuring myself of the feasibility of the feet (the drill passing through three deposits of clay undertaking, succeeded in inducing some of my neighbors to join with me in sinking an artesian well The enterprise was successful, and for the past three years the inhabitants of our city have been enjoying the privileges of some twenty flowing wells that furnish thousands of gallons per day of the purest natural water that I have ever used, it containing less than 25 grains of mineral substance (about one-half of which is chloride of sodium or common salt, and the remainder largely magnesia, with a small amount of lime and potash, not any of which in such very small quantities are objectionable) to the gallon, without a trace of organic matter also highly charged with static electricity or magnetism

Since this water became the common beverage I have been surprised and gratified to note the rapid improvement in patients suffering with chronic disease either of the liver or kidneys, and the almost entire absence of acute hepatic or renal disturb-My serious attention was first called to these facts by the continued failure to report at my office of a number of patients that had been under my When questioned in regard to their absence, they replied that they had been drinking fountain water, and felt so much better that they did not need medicine After carefully studying a large number of cases of kidney diseases and gouty tendencies in those who had been using a thorough course of these waters, and witnessing their rapid improvement, I am positive that the opinion expressed by my patients was well founded and in the main absolutely correct In other words, I believe that a large majority of these cases would make a rapid recovery if they would correct all the errors of their mode of hving sions, or in those occurring in the earlier months of

organic matter

Sometimes these patients are anæmic and require the exhibition of ferruginous tonics or other reconstructive, represented by some form of phosphorus, cod-liver oil, bark, etc Others may be suffering from some specific taint that will indicate alteratives in the form of the iodides, stillingia, hydrargyrum, etc., te, the appropriate medication I do not wish to be understood as condemning the employment of medicine in its proper place, far from it What I do wish to emphasize is this in these cases the most effectual way to rid the system of its accumulated load of waste material, and one that will not prevent the employment of any other, is to thoroughly wash the entire system (not simply the outside, until they appear like whited sepulchres, which indeed they are, full of dead men's bones and all uncleanness), but the inside as well, and at the same time stop their production and subsequent accumulation by the use of proper food, the observance of regular habits, with the continued ingestion of a sufficient quantity of pure water

After a careful and quite extensive examination of it passes for more than twenty miles, the absolute Early in the spring of 1883 I located in my present impossibility of its contamination, from the fact that the vein is tapped at a depth of not less than 150 that are impervious and insoluble, the aggregate thickness of which is 75 feet), and the absence of mineral deposits which might affect it, with a careful analysis, and the results of clinical experience, not a single case of malarial or typhoid fever or any zymotic disease having developed for the past three years among any of those who were using fountain water in our city

In view of all of these facts I am thoroughly convinced that it would be difficult, if indeed not impossible, to produce a water (either as a preventive or as a remedy in all hepatic and renal diseases, and This water is especially those that are characterized by an accumulation of waste material in the system) that would equal that which is discharged from the many flowing wells of the city of New London, Wis

> A CASE OF CEREBRAL LOCALIZATION, WITH DOUBLE TREPHINING (ACQUIRED SPASTIC HEMI-PLEGIA—PORENCEPHALUS)

Read before the Suffolk District Medical Society, January 11, 1888

BY W N BULLARD, MD, OF BOSTON

The case I have the honor to report to you to-night derives its chief medical interest from the fact that the diagnosis of the lesion, and the localization of its seat were correctly made during the life of the patient, and that the latter was such as could be easily reached by a comparatively simple operation Cases of operative interference in congenital cerebral leportance that the possibility of localizing these lesions, that is, anteriorly and posteriorly they be incapable of cure, their results can be mitigated, should be strongly emphasized Until of late years, but little attention has been paid to the various forms of congenital or infantile cerebral lesions, excluding hydrocephalus and inflammations of the meninges Patients suffering from congenital or infantile cerebral paralyses are too often considered not only absolutely incurable, but incapable even of improvement Some cases unquestionably are so, but on the other hand, I believe that in many of this class of cases we can do much to improve and mitigate those symptoms which we cannot remove, and there is no doubt that a broad field hes open here for cerebral surgery, provided only that the neurologist can state with some degree of precision the condition existing within the be moved somewhat, but is never used cranium, and if the lesion be a localized one, point out its seat

The present case occurred in the service of Dr Bradford, at the Children's Hospital, and it is through his kindness and at his suggestion that I bring it be-

fore you to night

The patient was a boy, $4\frac{1}{2}$ years old There was i no history of any nervous disease in the family, and no history of the patient was obtainable, except that he was supposed to have been in his present condi-The delivery was by forceps, and tion since birth the child had a scar and depression over the right parietal bone, supposed to have been caused by them There was no history of convulsions at any time The child was brought to the hospital by his parents, who insisted upon an operation—trephining over the depression-although they were informed that there was little hope of improvement from what they desired, and still less of cure This operation had been decided upon before I saw the child.

I first saw the patient at the hospital on the 22d of June, 1887, when his condition was as follows

The child was seated in bed As a rule, he sits quietly all day, doing nothing Expression vacant Intelligence limited, although he has a certain sense of his surroundings, as was shown by his screaming one day when he was placed in a bed in another part of the ward, and pointing with his finger to the old one, and continuing this until he was replaced understands simple words and sentences, and obeys simple directions He signifies when he is thirsty When told to do so, he will turn his head, and he will hand an object to a person, or smell of a rose, when it is suggested to him He can say "yes" and "no," and will say "good bye" when any one is going away, but he cannot talk He drules constantly

Physical condition Well nourished, well developed Head large, rather square On the right side, 5 cm behind, and about 4 cm above the upper edge of the anterior border of the pinna, there is a scar 5 cm long, extending forwards and slightly upwards This scar lies in front of the occipito-parietal depression, which is alike on both sides, and seems to cross the temporal ridge of the parietal bone, and the squamo-

life, are very rare, and I, therefore, believe it of im- and a depression with irregularities on each side, There is no deand the probability that in certain cases, even though cided tenderness here or elsewhere about the head Nothing else abnormal was detected about the

All the special senses appear normal There is right internal strabismus Eyes not examined oph-

thalmoscopically

Nothing abnormal could be detected about the trunk or organs of the thoracic or abdominal cavities There was an occasional reduplication of the first sound of the heart

The spine was straight, no tenderness in the back The patient cannot use any of his extremities, but he uses those on the left much better than those on

the right

Upper extremities The right upper extremity can It is in a The fore-arm is held condition of spastic paralysis semi-flexed upon the arm, and there is considerable resistance to passive motion, which can, however, be overcome after a time The hand is firmly flexed on the forearm He will not grasp anything with the He moves the left upper extremity right hand much better than the right, and always grasps objects with the left hand, and then holds them firmly

The right lower extremity is Lower extremities smaller, and possibly colder than the left There is a spastic condition of the knee and ankle The foot is held flexed in the equinus position, with the toes pointing downwards Some movement of the limb, however, is possible He can flex at the thigh, knee, and ankle when he wishes The left lower extremity is somewhat weak, perhaps from disuse, otherwise, nearly normal

Knee jerk exaggerated on both sides Patient is unable to walk or to stand without support He can take a step if supported under the arms, and he can hold his weight on the left leg. If the legs become locked at the knees, as they tend to do, he can support a portion of the weight of his body upon them The sensation is apparently normal everywhere throughout the body Nothing else abnormal detected

To resume the case in short, we have here a boy four and a half years old, with much diminished in-He telligence, inability to speak, inability to use any of his limbs well, and with right internal strabismus and right spastic hemiplegia In addition, there is a wellmarked cicatrix and depression in the right posterior parietal region

After examination of the case it was decided, at my suggestion, that in addition to the operation already proposed, the cranium should be opened over the cortical motor area of the left side, as this seemed

to offer the strongest prospects of relief

The operation was, accordingly, performed on the 27th of June, by Dr Bradford The patient being etherized, the various points were localized on the shaven head, and the position of the fissures of Rolando determined as carefully as possible Dr Bradford trephined first on the right side of the head, parietal suture On palpation, there is an irregular directly over the cicatrix A curved incision with its knob or prominence under one portion of the scar, convexity downwards, about six inches in length, was made through the scalp, the periosteum was removed and I believe it to be the duty of the neurologist, so intact, and the cranium trephined—the trephine used far as lies within his power, to improve and perfect being an inch in diameter. The outer table of the his knowledge, so that, when appealed to by the surportion of bone removed showed a fracture, and the geon, he shall be able to point out where the instruinner a slight inequality, due to a fissure mater exposed was thickened and its vessels filled lesion is likely to be found with blood It (the dura mater) was then incised, and the brain and pia exposed to view There was no evidence of pressure, nor of anything abnormal least—can be reached by surgical interference with The brain protruded slightly here below the dura through the opening and pulsated [It is important longer be regarded as a serious operation in ordinato note here the fact that, in spite of the fracture of the cranium, and the accompanying thickening of the dura mater, the pia and brain were, as far as could be told, absolutely normal 7

It was now decided that it would be wise to trephine over the probable seat of the lesion on the left side, and, at Dr Bradford's request, I located the motor area on the left side, where it was presumable, from the symptoms, that the lesion would be found This point was a little higher and slightly further forward than that trephined on the right, at the junction, as nearly as could be determined, of the middle and lower thirds of the fissure of Rolando There was a very small superficial cicatrix in the skin here, not involving the deeper tissues of the scalp, and which had remained undetected until the position was marked An incision similar to that made on the right side was now made here cranium, when uncovered, appeared perfectly nor-It was trephined, and, on the removal of the bone to which the dura was attached, a depression in the brain substance—porencephalic cavity—was This not only occupied the whole space directly under the opening, but also extended some-The pia seemed to be adherent what anteriorly The brain substance in this depression, which was estimated as about 11/2 inches long, by 3/4 inch wide and 3% inch deep at the deepest part, was puckered and shriveled Considerable hæmorrhage from the to perform two operations bone followed the removal of the button on this side This was quickly controlled by plugging

As the patient's condition was poor—pulse very weak, and respiration slow and labored—nothing fracture or visible injury on one side, the actual cere-After replacing the buttons further was attempted of bone on each side, and stitching the dura mater on the right, the incisions were sewed up, and bandages and dressing applied

The patient, however, never rallied thoroughly after the operation, although he recovered consciousness in the evening, and was conscious until the following morning, when he died at 10 A M, about seventeen hours after the operation The temperature was not taken on the evening following the operation, but the next morning rose to 105° There was no autopsy

This case, it seems to me, illustrates some interest-In the first place, it demonstrates the possibility of localizing lesions of this character (porencephalic) in children in certain cases is, of course, the first step in any rational attempt That these lefor their direct alleviation or cure sions can be localized with moderate accuracy at least, sufficiently for all practical purposes in a large proportion of the cases of this class, I am convinced, an association formed in London on February 13

The dura ment should be directed, and to state what sort of

Secondly, I believe that this case may be accepted as evidence that these lesions—many of them, at out serious difficulty, since simple trephining can no rily healthy persons If this be true, its importance is at once manifest If these lesions can be localized, and if surgical interference in them is not a matter of serious difficulty nor of marked risk to the life of the patient, we have here at least one expedi ent which offers a prospect of alleviation in these cases, however remote

It is well known to most of us, but I repeat it here for the sake of emphasizing it again, that there are no cases which, as a class, are regarded by the whole medical profession as more utterly hopeless and as more entirely beyond any possible medical aid and assistance than congenital and infantile brain affec-There is no class of cases in which the pa tients are more utterly useless to themselves and to the world, or more of a burden to their parents and relatives Anything, therefore, which affords the The least prospect of relief, is in them of the utmost importance

There are two other points in this case which are of both neurological and surgical value, which I will refer to in short

The first is the question of the advisability of trephining in more than one place at the same time in Whether, in this case, the result might children have been more favorable had the operations been performed separately, it is impossible to decide, but in a similar case it would certainly seem more safe

The second point is one which, although theoretically well known, cannot be repeated too often, and This is that, in spite of a it is well illustrated here bral lesion may be upon the opposite, whether produced by direct violence or by contre-coup fore, in case of cerebral injury, if the symptoms point to a lesion on the opposite side from the trauma, for example, if the hemiplegia is on the same side of the body as the fracture of the cranium, we should not trephine at the place of fracture, but on the other side

In the case of our patient, the probability is that the whole trouble was traumatic, and due to the pres-While on the right the parietal bone sure of forceps was fractured, on the left, the bone being more yielding or the blade being in a slightly different position, or for some other reason, a different effect was produced This was probably the rupture of the ascending parietal artery or one of its branches

THE BRITISH NURSES ASSOCIATION IS the name of

THE USE OF SACCHARIN IN DIABETES BY CHARLES W PURDY, M D,

OF CHICAGO, ILL

HON FELLOW OF ROYAL COLLEGE OF PHYSICIANS AND SURGEONS, LINGSTON ONT

Sufficient time has now elapsed since the introduction of saccharin to permit extended observations of its physiological effects upon the organism, as well as to learn something of its therapeutical properties. This time, happily, has been improved by numerous observers, especially by Stahlman, Salkowski, Stutzer, Adducs, and Leyden, to whom we owe much of our knowledge upon this subject

We know that this agent is absolutely innocuous to the system, even when administered in sufficient quantity to equal in sweetening power three pounds of sugar a day, and continued indefinitely. The fact that large contracts have recently been made for the supply of saccharin for military use, both by the German and the Russian governments, indicates clearly its harmlessness as a flavoring agent for food and drink

With an agent so harmless, and possessing a sweetening power more than three hundred times that of sugar, we naturally turn to diabetes as a useful field for its employment, since the deprivation of sugar always so essential in successfully treating these cases—is often one of the severest trials to the patient in the enforcement of the diabetic dietary. Simply as a flavoring agent saccharin leaves little to be desired as a substitute for sugar, save its sparing solubility. It is of course entirely devoid of nutritious properties.

From a liberal use of saccharin in my practice since its introduction I have not yet met with a single instance in which its palatability was suggested as in the least inferior to that of the purest sugar

The most desirable form for the use of saccharin by diabetic patients is that of tablet, since in this form a combination may be made—usually with an alkaline carbonate—which renders the saccharin perfectly soluble in water I have made numerous trials and experiments with the several forms of saccharin tablets at present on the market, both here and in Most of these have been found quite soluble, but they contain rather an excess of saccharin which I think in some respects objectionable From a grain to a grain and a half of saccharin will render a cup of tea or coffee about as sweet as will two lumps of white sugar, and I find that while most patients crave the flavor of sugar, some resent an excess of it, and therefore the tablet must be broken—and consequently in part wasted—in order to get the desired grade of flavor The tabloids I am now using are made for me by Parke, Davis & Co, of Detroit, and contain each 25 milligrammes of saccharin, in the shape of soluble salt, and these give entire satisfaction

In addition to its use as a flavoring agent for food and drink saccharin possesses properties that render it valuable as a medicinal agent in the treatment of diabetes. It possesses decided antiseptic properties,

1 One part of saccharin can be distinctly tasted in 10 000 parts of water

estimated by trustworthy observers about equal to that of salicylic acid and thymol On the other hand, saccharin exerts no action on ptyalin or pepsin, and, moreover, it seems to have no secondary action on the digestive secretions—passing unchanged through the organism, to be eliminated by the kidneys, as do benzoic acid and resorcin—imparting its antiseptic properties to the urine

In diabetes, as is well known, the necessary ingestion of a food mostly of a nitrogenous character often weakens the digestive power of the stomach and flatulent dyspepsia is the result. Now in saccharin we possess an agent that very much retards the abnormal fermentative changes in the stomach, and its tendency therefore is to preserve the food from such changes until the tardy flow of gastric juices finally reaches and digests the whole contents of the stomach—just as does carbolic acid and such

agents relieve flatulent dyspepsia

We are perhaps justified in looking for another possibly beneficial action of saccharin in diabetes, based upon its antiseptic properties, though thus far our knowledge rests mostly upon a theoretical foun-When we consider the strong tendency to fermentative action in the blood of diabetic patients, as is evidenced by the frequency of multiple furunculus and anthrax, as well as Kussmaul's coma, we can scarcely resist the conviction that the passage of such an antiseptic as saccharin through the bloodespecially in large doses—cannot but have a modifying influence upon these fermentative changes Theoretically then at least, saccharin if given in considerable quantities might be expected to exert a most beneficial influence over those blood changes in diabetes from whence spring complications comprising the most serious and fatal features of the disease

In brief, then, we are justified in the following conclusions in reference to the use of saccharin in diabetes

First, that in this product we possess a flavoring agent for food and drink the palatability of which is quite equal to that of the finer grades of sugar, and which may be used by diabetic patients with the greatest impunity

Second, that through its antiseptic properties it retards the abnormal fermentative changes in the stomach so common in diabetic patients—thus pro-

moting digestion and relieving flatulence

Third, that while as yet we are without sufficient practical data to judge of its blood effects in large doses to diabetic patients, yet both chemistry and physiology would indicate its use for the purpose of favorably influencing some of the more fatal complications of the disease

163 State St Chicago, Feb 13 1888

PROFESSOR NAUNIN, lately appointed to the Chair of Medicine in the University of Strassburg, will begin his course on April 1 For his vacated chair at Konigsberg the names of Strumpell, Quincke, and Lichtheim are mentioned

MEDICAL PROGRESS.

ANTIPYRIN IN MIGRAINF -DR W H RUSSEIL Forsbrook has prescribed antipyrin in 100 cases of have been much used in this disease. When it has He has found that antipyrin given in 15grain doses every twenty minutes, three times consecutively, almost invariably removes the pain, depression, drowsiness, and nausea, so that in forty have had an opportunity of treating as many as minutes, frequently even after one dose, patients express themselves quite well A single dose, if given during the premonitory signs, will often ward off an The few cases that are not amenable to the speedy action of the medicine, appear to have the duration of the attack much shortened Further, the period between the attacks has seemed to be prolonged, and succeeing attacks have not been so The pulse, which is generally slowed during an attack of migraine, appears in some cases to be rendered fuller and quicker to young women for migraine, sometimes produces a species of intoxication, so that it is as well to be on one's guard, although, as far as his experience goes, the only result has been the almost certain and immediate relief from the peculiar pain Lancet, December 10, 1887, p 1163) During the last two month, Dr Kingsbury, of Blackpool, has treated twenty cases of migraine with antipyrin Several of the patients had suffered for over ten years, and, finding all drugs useless, had become reconciled to being periodically prostrated for one or two days In all the cases he ordered 8 grains of antipyrin, dissolved in water or lemonade, to be repeated every half hour, the patient lying down Most of the cases were quite cured by two powders, the most obstinate yielded to three, in no case did A cup of warm tea sometimes the antipyrin fail seemed to help, and the only inconvenience due to the treatment was, in a few of the cases, considera-Many of the patients could hardly credit that instead of being utterly helpless for twenty-four hours, they could now cut short an attack in one hour Another great advantage of antipyrin is that it prevents as well as cures these at-One lady, who cannot remember having fewer attacks than three a month, each lasting about thirty-six hours, has been quite free for eight weeks, and this she attributes solely to the occasional use intellect of antipyrin powder (Brit Med Journ, December undue fatigue, and is attended with a good deal of 24, 1887) In a letter on this subject Dr N E Davies says that in the cases where he has tried it attack and promptly administered antipyrin the effect of antipyrin has simply been marvellous In one case of a lady, who for years had been the subject of most distressing periodical attacks of intense pain referred to the occiput that defied all whom the fits are preceded by a well-marked aura in ordinary remedies, this drug relieved at once, and the depressing fear of impending attacks disap-It leaves no ill effects whatever-a great Ten grains repeated every hour for desideratum two or three hours is his plan of giving the drug, and then at intervals of six hours for a day or two after to prevent all chance of a recurrence, this generally being at the desire of the sufferer

MR T J BOK MHAM says

the past few months attracted considerable attention in Germany on account of its astonishing action on the paroxysms of migraine In England, however, until quite recently, the drug does not appear to been tried at all, the doses given have been large, and have in some instances been found to produce unpleasant effects During the last two months I twenty-six cases of migraine with antipyrin results have been in every case perfectly satisfactory. although the dose given has been quite small, in no case exceeding 4 grains I will only describe three typical cases namely that of a near relative that of a girl, members of whose family exhibit epileptic tendencies, and an attack as occurring in myself

My own migraine is usually brought on by over-use of the eyes, and is almost invariably preceded by well-marked teichopsia, which lasts for from half an Antipyrin, when given hour to several hours As the attack proceeds, I get a tender spot on some part of the scalp, generally on the right parietal region, a vascular disturbance, with throbbing behind the right eye The first time I took antipyrin it was in a dose of 3 grains after the pain was well developed. In a very short time the throbbing entirely ceased, leaving only a dull aching pain behind the eye, the flushing of the face also diminished After half an hour I took a second dose of 3 grains, and by the end of an hour from the time of taking the first dose was quite well, save for slight tenderness of the scalp Since then I have tried the drug, in the same dose, taking it immediately the teichopsia comes on, with complete success in altogether preventing the attack

The second case is that of a lady who has been subject to attacks of migraine for many years ing point of her attacks is also in the eyes For a long time large doses of ammonium bromide were successful in cutting short the attacks, but recently this drug seems to have lost most of its power Antipyrin entirely relieved the prostration and pain

after the second dose of 3 grains

The third case is interesting in that it points to another class of cases in which antipyrin may be of use, namely epilepsy Here the mother is epileptic, the father is of a very excitable temperament, and another member of the family shows signs of weak In this case migraine usually follows any prostration I happened to be with her during ore headache yielded entirely after the second dose of 4 grains

I have under observation also two epileptics, in the shape of tingling of the extremities of the fingers They are directed to take, immediately they feel this sensation, 10 grains of antipyrin in a little water If the theory of Dr Liveing concerning the close pathological relation between migraine and the other so-called paroxysmal neuroses be true, there is some hope that in both these diseases we may be able to check or to cut short the attack by the Antipyrin has for timely use of antipyrin I have not yet had the opportunity of observing the effect on these two pus, from which no bacteria could be obtained

The plan I have pursued with so much success in this series of cases is to give very small doses, contrary to the practice of most physicians, who have reduced the tissues to a soft hæmorrhagic mass used as much as 15 grains repeated every twenty minutes. I feel sure that antipyrin requires only to ment of migraine and that practitioners will use the small dose with less hesitation than they would the large ones previously given -The Practitioner, February, 1888

Causes of Subcutaneous Inflammation and Suppuration -Grawitz and De Bary (Archiv für Patholog Anat u Physiol u für klin Medicin, Bd 108), report some experiments showing that the introduction of pus bacteria into the subcutaneous tissues is not in itself sufficient to cause suppuration, but that other factors must be present to furnish a suitable condition for their growth and multiplica-In their experiments they carefully cleansed and disinfected the integument at the proposed site of injection, used a thoroughly clean needle of small. caliber, and immediately closed the wound made by the needle with iodoform collodion It was found that with these precautions large quantities of neutral fluids were absorbed after subcutaneous injection, both when sterilized and when infected with the Staphylococcus pyogenes aureus or cureus to a greater extent than the most careless experimenter would tive inflammation ever accidentally infect sterilized fluids They therefore consider the wound made by the needle to be the point of danger, as the bacteria are held here, multiply, and spread through the tissues, while those in the meshes of the subcutaneous tissue are absorbed before they can do damage In this way they explain the observation of Uskoff that suppuration was produced by the injection of large quantities of neutral fluids, and negative the assertion of Orthmann that the suppuration so produced was due to the admixture of bacteria In some cases the mtegument over the injected fluid died, and in these cases suppuration occurred Histologically, the connective-tissue cells at the site of the injection were plainly seen in the sheaths of the neighboring nerves, demonstrating that narcotic substances so injected this wire severs that part of the organ probably exercise a local effect Subcutaneous ina solution of bichloride of mercury (1 to 1,000), ab solute alcohol, and tincture of iodine-were followed by severe inflammation, but no suppuration unless the integument became necrotic After successive injections of solutions of chloride of zinc, varying these is, I conceive, a very great gain from 1 to 5 per cent, into the same portion of a muscle of a rabbit, a fluid impregnate with Staply there was no pus After the injection of a few centimetres of a 5 per cent solution of nitrate of silver into a dog, an abscess was formed containing | 147

epileptics, but it would certainly seem to be worth a solutions not germicidal, but able to arrest the development of bacteria, acids and alkalies produced no suppuration, even after the addition of bacteria, though 5 per cent solutions of the caustic alkalies jections of 1 to 4 solutions of ammonia caused the minutes I feel sure that antipyrin requires only to formation of pus, cultivations of which in agar agar be known to become a regular remedy in the treat-remained sterile. When bacteria were injected with it, flourishing colonies of the same form of bacteria as those injected could be cultivated from the pus Hence they conclude that ammonia, in sufficient concentration to cause severe inflammation and suppuration, furnishes in the subcutaneous tissues a suitable material for the growth of bacteria. Oil of turpentine they determine to be a germicide of the Instruments immersed in it for two first rank minutes are, they maintain, absolutely aseptic, and are not injured as by solutions of bichloride of mercury and carbolic acid Injections of this oil failed to produce suppuration in rabbits and guinea-pigs, but in dogs abscesses were formed which contained a peculiar pus with no bacteria Small amounts of croton-oil produced fibrinous exudations, but no pus, larger quantities caused poisoning These observations show that certain chemical substances, in the right quantity and strength, can, without bacteria, produce suppuration in certain classes of animals, or may render the tissues suitable for the growth of bacteria which, injected alone into the normal subcutaneous tissue, cannot, unaided, cause a suppura-

A METHOD OF Excising the Tongue -In a clinical lecture Mr Richard Barnwell describes the following method Strictly in and along the middle line an opening is made about one-third of an inch long immediately in front of the hyoid bone, through the raphe of the mylo hyoid The geniohyoid and genio-hyoglossus muscles are separated with the handle of the scapula until the deep surface of the mucous membrane forming the floor of the mouth is reached By means of Liston's needles carried under this membrane to, or even beyond, the last molar teeth, threads are passed on each side into the buccal cavity, which in their turn draw found swollen and nuclear When the solution had flexible wire-twist, first into, then out of, the mouth, been colored with methyl-blue, the coloring could be in such wise as to surround the base of the tongue as far back as one will An écraseur working with Then the loop of another écraseur is passed between the jections of certain germicidal irritant fluids-such as teeth, pressed well down on the first incision, and divides the structures beneath the tongue

The advantages are the bloodlessness of the operation, its great security against septic pneumonia, and the painlessness of the stump The first of four drops of blood come from the skin of the suprahyoid wound, and only enough should be produced lococcus p) ogenes aureus was injected into the same from the tongue to stain slightly the saliva. It is, place. The muscle was found disintegrated, but however, right that I should tell you of an objection that has been urged against this procedure—viz,

¹ See my paper in the Clinical Society's Transactions vol xit,

that if in the first section by the Coraseur any con-diarrhoea, dysentery, phthisis, etc siderable hamorrhage should occur, the bleeding nance to and intolerance of food in almost every vessel would be inaccessible, the tongue being yet in form, which do not always yield to acids, bitters, and The matter, however, hes entirely in hux vomica as usually given the mouth the hands of the surgeon, for the fact is that unless bis in small doses—m, v-x of the tincture, or gr 1/4-1/2 the ecraseur be worked with culpable rapidity there of the catract—has been found very useful. The is never any bleeding worth mentioning, since no tincture may be given in emulsion, with a small quanlarge vessels are here divided Moreover, the tight- tity of mucilage and simple syrup, and flavored with ening of the écraseur wire produces that very compression of the base of the tongue which Mr Heath has shown can be effected by two fingers introduced sugar, gum acacia, etc., to proper consistency The into the pharyn, and which he points out will check mixture or lozenge may be given three times a day, I have operated by Whitehead's and half an hour before meals hæmorrhage by Baker's method, and have more often seen those One of my objections to operations performed both is that an unnecessary amount of blood is lost The former method especially requires a particularly good light, and a patient quite under anæsthesia, and able to open widely the jaws—a condition not by any means always present Moreover, neither of these operations provides for draining the cavity, therefore foul saliva and pus accumulate at its back and in the fauces, is even apt to dribble stages of tropical diarrhœa cannabis is sometimes down the laryn, and at least infects the passage useful through which the breath passes to the lungs In essentially of the liver, and cholagogue remedies my operation the supra-hyoid wound forms, if the must be used patient's head be slightly raised, the funnel-like bot- as blue pill or gray powder The mercury is given tom to a cavity perfectly drained through that open- at night, and the cannabis during the day Begin I have never found it followed by septic pneumonia, and am glad to hear my patients complain, as they always do, that the mouth is dry also been urged that this method does not provide for excising diseased glands Well, that is true both of this and of the other two procedures I have men-Superficial glands must be removed separately, the only plan which is adapted for the removal of the tongue and of deep glands is Kocher's exceedingly severe operation

And now about the painless condition of the The chief, if not the entire, tactile sensibility of the tongue is derived from the gustatory branch of the fifth, for this sense in the glosso-pharyngeal twig is very dull and obscure The lingual gustatory reaches the tongue by passing down on the ramus of the lower jaw, and division of it in that part of its passage is a device for rendering the organ insensi-Now the first cut of my écraseur divides these nerves from the point where they leave the jaw, or more often the wire does not cut them, but isolates them, leaving them as branched white threads loose in the mouth, in which case they are to be snipped off with scissors close to the bone, either way the stump has no sensory nerve, and thus is painless, to the great comfort of the patient -Lancet, Dec 31, 1887

Uses of Cannabis Indica —Surgeon-Major J F P McConnell, of the Bengal Service, in an article on this subject in The Practitioner, of February, 1888, speaks of some uses of cannabis indica One of that do not seem to be generally known the conditions in which the drug has proved useful in his hands is anorexia—loss of appetite consequent gum tubing of different sizes and strength and made upon exhausting diseases, such as prolonged fevers, applicable to each case by such impromptu means as

There is a repug-In these cases canna-The extract may be given in lozenge rose-water or bon-bon form, after being rubbed up with white

Another condition is dyspeptic diarrhaa, and the diarrhœa that is associated with defective action of the liver and deficient secretion of bile, and that tends to diarrhœa alba (tropical diarrhœa, in which there is a tendency to action of the bowels soon after meals, and a consequent hurrying of imperfectly digested food through the bowels In the earlier stages of this disease cannabis is often of great service in controlling the diarrhea Even in more advanced The disease seems to be one primarily and Of these mercury is most reliable with mo of the tincture, and gradually increase the dose to may, ax, or ax, three times a day or It has oftener A suitable combination is

Tincture cannabis indica.	mx-\:
	•
Subnitrate bismuth	gr \
Mucilinge of acricia	35°
Comp spts chloroform	m,,
Cinnamon or peppermint water	Ē)
7tp	

Give before or after food, preferably after, especially when the dose is increased, since in this way unpleasant symptoms are obviated

Both in tropical and in dyspeptic diarrhœa cannabis is better than opium because it in no way interferes with the bile-forming function of the liver But when tropical diarrhœa has gone so far that the functional disorder of the liver is succeeded by organic changes, cannabis is useless

A third condition in which cannabis is useful is in cases of chronic cardiac disease, and in chronic Bright's disease as a hypnotic In cases of distressful insomnia and general inquietude, with an enfeebled heart, in which chloral seems inadmissible, the administration at bedtime of Mav-ax of tincture of cannabis, with a small dose of chloral (gr) and 3ss of bromide, will often give the desired effect

NASAL INTUBATION -DR D H GOODWILLIE, IN a paper read before the Section in Laryngology and Rhinology of the New York Academy of Medicine, December 27, 1887, described a method of nasal intubation as a valuable aid in the treatment of intranasal disease

My first efforts began by the use of pure rubber-

These experiments, after being I had at command I had the tubes made in soft rubber and platinum or aluminium from models that have proved by experience to be of practical application These improved tubes properly made have given me good results

of different sizes, one fourth to one-half inch in diand one-half inches, but may readily be cut to any The metal tubes can be changed in desired length desired shape The anterior end may be soft rubvestibule of the nose changed to larger ones until there is normal space the nose and mouth or the deformity has been corrected freer respiration through them passing it into the inferior meatus, then releasing the was drawn upon end of the nose and passing the anterior end into curred after the first twenty-four hours so can be worn and treatment carried on without any unsightly appearance, or even knowledge of They can be readily removed by their presence the patient for cleansing and returned to the nostril Some of my patients have worn them constantly for months without discomfort and always with benefit

I will simply refer to some of the nasal diseases in which they have been made use of—viz

Intranasal hæmorrhage

2 Fractures of the nose, internal and external

3 Deviations of the cartilaginous and bony septum after the necessary surgical operation of section or removal of exostosis

4 After the removal of hypertrophic turbinated tissues or polypi, whether by the cautery or snare

5 Hypertrophies of the soft tissues without an operation, when worn for a sufficient time to pro duce absorption -N Y Medical Journal, February

TREATMENT OF CAROTID HEMORRHAGE -In a short article on this subject, in which he reports 4 cases, Mr Frederick Treves says

In the neck, pressure upon the carotid artery cannot be applied with success, or maintained for a serviceable length of time The vessel can, however, be very readily occluded for a while and the carotid circulation arrested without the artery being permanently closed This is effected by exposing the By pulling upon the loop the circulation through the vessel is at once arrested, but is, however, at once restored when the tension upon the loop is

The following case, in which the method was used, is especially interesting

A builder, æt 41 years, a man in excellent health, carried on for some time, were so encouraging that | met with the following accident On Dec 7, 1885, he fell from the scaffolding of a house in process of erection, a height of 26 feet He alighted upon the iron railings around the house, the points of these railings were in the shape of spear heads, and one of These tubes are oval in shape and of the same them penetrated his skull. The point entered just in size, with the exception of the anterior end, that is front of the left ear, and, passing through the maxilshaped so as to fit the vestibule of the nostril, and lary bones, emerged through the hard palate of the by that they are retained in place They are made right side, and, entering the mouth, broke one of the right upper molar teeth The railing, having impaled ameter, and in length from two and one-half to three the skull in this way, snapped off short, and the patient fell on the pavement with this enormous foreign body in his head The piece of iron actually within their caliber by passing through them a core of the the head measured five inches and a half in length, two inches and three quarters in breadth, and from ber, as it is more comfortable by its flexibility in the half to three quarters of an inch in thickness. There The small rubber tubes are was very free bleeding after the iron was removed, made use of at the beginning of the treatment and blood welling up from the wound and running from No pulse could be felt in the Then the left temporal artery, and it would seem pretty certain metal tubes may be used if so desired, as they allow that the external carotid artery had been torn across The tube is put into I at once put a catgut loop around the common the nostril by raising the end of the nose and gently carotid, and the bleeding was stayed when the loop No bleeding of any moment oc-On the They can not be seen externally, and fourth day a weak pulse could be felt in the left tem-On the seventh day the catgut loop was reporal The carotid wound healed without complimoved cation The man did well, and was able to leave the hospital some six weeks after the accident —Lancet, January 21, 1888

SUCCESSFUL EXCISION OF A TUMOR OF THE SPINAL Cord —Surgery is a science, or perhaps we should say a fine art, which will tolerate no limits to its do-It has of late taken up the invasion of the brain in earnest, it has just made its first successful dash at a tumor in the spinal cord Last Tuesday evening, before the meeting of the Medical and Chirurgical Society, a private patient of Dr Gowers and Mr Victor Horsley very generously allowed the Fellows and visitors of that Society the opportunity of seeing all that had been done for the improvement of his condition He had spent about three years in severe pain, which was most intense just below and inside the angle of the left scapula, and was accompanied by absolute loss of motion and sensation of the body and limbs below that level The upper border of the an esthesia was distinctly in the region of the fifth intercostal nerve on the le side, on the right it was less accurately defined, but did not extend higher All the symptoms agreed with those of tumors of the spinal cord, and the intense pain afforded ample justification for making an attempt to excise the tumor Mr Victor Horsley artery in the usual way and passing around it a thick accordingly removed the spines and parts of the piece of soft catgut. This is tied in a very loose laminæ of the fifth and fourth dorsal vertebræ, but not until the third vertebra had been similarly treated did the tumor come into sight It was a small oval myxoma compressing and making a deep impression on the left side of the spinal cord below the third vertebra It was easily shelled out, and under careful antiseptic treatment the temperature

did not rise more than 1° F rapidly, except at the uppermost point, where a rest to that organ, and by no other means drain had been left in by which a little cerebro-rectal alimentation we have a safe and sure means of spinal fluid flowed away very slowly four weeks the former acute pain did not lessen, and that organ — Dietetic Gazette, January, 1888 even at times seemed more agonizing, but after that it gradually and intermittently decreased, and now, after seven months, is entirely gone, the sensation and motion of the body and legs are almost com-pletely restored This is, we believe, the first time pletely restored that such an operation has been attempted, and we must, most heartily congratulate both the patient and his advisers on the triumphant character of its However far, and however quickly surgery may advance, it will long be a memorable day when it gained its first victory on so new a field and over so formidable an enemy -British Medical Journal, Jan 28, 1888

RECTAL FredING —From a study of the subject of rectal alimentation, DR WEAVER (Transactions of the Luseine County Medical Society) has formulated the following conclusions

1 By the use of enemata life can be sustained indefinitely with little, if any, loss of weight to the body

2 In a large proportion of cases in which rectal aliment is used, true digestion of albuminous, saccharine, and fatty food takes place, by virtue of inhaustion, or a reversal of the normal peristalsis of the alimentary tract

3 While this is the case, there are doubtless instances in which retrostalsis does not occur, and for that reason the food used should first be artificially digested before being injected into the rectum

4 While milk, eggs, and brandy are the best aliment for rectal nutrition, no one article should be used for too long a time, but frequent changes should be made, observing the greatest care to prevent irritation of the rectum, or intolerance of that organ for the nutriment required

5 The enemata should, if possible, be administered by the physician himself Where difficulty in retaining the aliment is encountered, the colonic method is preferable, the food being propelled through a rectal bougie temperature of the body

7 The rectum having once become intolerant of enemata, absolute rest must be given to that viscus for a few days, and reliance be placed on nutritious inunctions of the surface of the body

range of usefulness than has heretofore been as-It is not only appropriate in the ical scraping severer forms of chronic disease of the stomach and removes the thickened epithelium, in order to acesophagus, but is indicated and should be utilized in complish this several sittings may be required the management of all acute diseases when, from any cause, the stomach become intractable and rebellious

8 In diseases of the stomach, even where a portion of the food ingested is retained by that organ, only to undergo fermentation, inducing thereby glycerine, glycerine of borax, or a 10 per cent solupain and distress, it is more logical to resort to rectal tion of sulphate of copper is applied to the raw alimentation, not as an adjunct to, but a substitute surface for stomachal ingestion

9 Certain organic lesions as well as functional Lancet, Jan 7, 1888

The wound healed disturbances of the stomach are curable by means of For three or nutrition, pending the necessary period of rest to

> COLCHICUM IN THE URIC ACID DIATHESIS —In an address on the Therapeutics of the Uric Acid Diathesis DR I BURNEY YEO says that Dr Bartholow's description of the effects and uses of colchicum is

so complete that he has little to add to it

"The prejudice against colchicum has induced Ebstein to make the extraordinary statement that it is preferable to relieve the pain of the gouty paroxysm by hypodermic injections of morphine. He says they act "quicker, more easily, and with less danger The internal use of I join issue with him utterly opiates in gout I consider, except under exceptional In a disease of defeccircumstances, indefensible tive elimination, you would be giving a drug which depresses in a remarkable manner the function of all the excretory organs but the skin A very small dose of morphine will, especially in the gouty constitution produce clay-colored alvine evacuations, sometimes for days

Colchicum then, I maintain, is one of the most valuable remedies, when judiciously given, for most of the morbid manifestations of this "unc acid diathesis," and so far from being a dangerous vascular depressent, I have shown, in my hospital practice during the session just passed, that in a case of chronic gout with subacute exacerbations, moderate doses of colchicum restored regularity and strength to an irregular and feeble pulse I trust, then, that the absurd prejudice against this most valuable remedy which has been excited in the minds of the public will be removed, for I find many gouty persons who, much to their own disadvantage, positively refuse to to take colchicum, because they have been told it is, "such a dangerous drug"-British Medical

Journal, Jan 14, 1888

MECHANICAL TREATMENT OF SYPHILITIC ICHTHYO-The food should be of the sis -The syphilitic affection of the tongue and mouth known as keratosis or ichthyosis linguæ, or as leukoplakia specifica, which is due to unequal development of epithelium over different papillæ, and which is by no means a very easy affection to treat successfully, caustic, astringent and disinfecting ap-7 For rectal alimentation there exists a wider plications having but very little effect upon it, is, according to DR Horovitz, best managed by mechan-He uses a sharp spoon with which he scrapes away the indurated tissue until the surface presents the appearance of a multitude of minute bleeding points showing that the vascular loops in the papillæ of the dermis have been reached The pain is usually not severe, but in the case of sensitive persons cocaine can be used -

NEW YORK STATE PROVISION FOR THE INSANE

The State Charities Aid Association of New York has recently done a very good work by the preparation of a bill, for introduction into the Legislature, that provides for the gradual transfer of the insane, both acute and chronic cases, from county and city poorhouses into the care of the State Its prominent features are as follows

- 1 The districting of the State into as many asylum districts as there are State Hospitals for the insane
- 2 The reception by the State Hospitals of all the pauper insane from all the poorhouses of the districts to which the State Hospital belongs, at a uniform weekly rate per capita, charged to the counties, for each pauper insane person so received, whether an acute or chronic case, of \$1.50. This payment includes clothing and travelling expenses, and the sending of a trained attendant to accompany the patient to the hospital. All cost of care and maintenance exceeding this rate is to be paid for by the State at large.
- 3 The erection on the grounds of the existing State Hospitals of a number of inexpensive detached buildings, sufficient to provide suitable accommodations for the chronic pauper insane now in the poorhouses of the State, at a cost not to exceed \$250 per capita These buildings to be erected, if possible, within one year after the appropriation is made

The elastic nature of the proposed measure, by which present and future needs are provided for, as regards overcrowding, size of buildings, etc., is an important feature, and it is to be hoped that this act will be passed, as it is beyond question that the insane

can be cared for much more satisfactorily in every way by the State than by the counties individually, the State hospitals representing to-day the very best standard of treatment that has been reached in this country. In addition, it is highly desirable that the measure should be adopted at this time, for a movement is on foot, backed, it is said, by certain local political influences, to secure special legislation by which a number of the counties in the State shall be empowered to take care of their own insane in county asylums.

At the recent meeting of the Medical Society of the State of New York, the President, Dr Alfred L Loomis, referred to this matter in his address. He contended that experience universally condemned the advisability of such county asylums, and recommended that the Society should take action upon the subject. The special committee appointed in accordance with the suggestion made in the address, consisted of Drs A Jacobi and C R Agnew, and they prepared the following very admirable report.

- r That until comparatively recent times the insane were considered and treated as criminals and confined in dungeons or prisons
- 2 Their subsequent retention in poorhouses was but a remnant and mitigation of the old system
- 3 The treatment of the insane has improved with the progress of civilization
- 4 Therefore special hospitals were supplied for them, and their welfare was entrusted to scientific and humane experts
- 5 To return to anything like the old system of treating the insane in poorhouses or relegating them to the custody of county officials, would be a grave mistake. As early as 1855, at a mong of the County Superintendents of the Poor, held t Utica, the following, among other resolutions, was assed
- "Resolved, That no insane person should be treated, or in any way taken care of in any county poor or alms house, or other receptacle provided for and in which paupers are maintained and supported" (55th Annual Report, State Asylum, at Utica)
- 6 For the proper classification and treatment of the insane more means are required than for the patients of general or even other special hospitals. Institutions for the insane, therefore, demand medical experts as superintendents, nurses trained in the general care of the sick and then in the special care of the insane, schools for the physical and intellectual training of the insane, for the practice of out-door and in-door industries, and many other appliances
- will be passed, as it is beyond question that the insane expresses, therefore, its objections to any plan or

law which in any way looks to the return of the insane to the county poorhouses as being unscientific and inhumane, and expresses its convictions that those institutions, like the State Asylum, which have Boards of Managers accountable to the State Government, and also to the public, are best adapted for the care of the insane poor of the State

This report was adopted by the Society, and also the following resolution

Resolved, That the above report on the treatment of the insane be sent to the Committee on Legislation of the Medical Society of the State of New York, with instructions to use it in its discretion, in the Legislature and elsewhere, to further the objects in view

In the discussion upon the resolution the following extract from a letter of Dr Jos M Cleveland, Medical Superintendent, Hudson River State Hospital, Poughkeepsie, N Y, to Amasa J Parker, Jr, President of the Board of Managers of the Hospital, was read as illustrating the progress that is being made in the scientific nursing of the insane, a kind of progress not likely to reach the insane if shut up in poorhouses

"Next month, (March, 1888,) we graduate four young women from our Nurse's Training School All four before coming here had graduated from a General Hospital Training School They will have been with us one year in March They have been very thoroughly instructed in mental nursing by lectures, class instructions, quizzes and clinical teaching They are bright, intelligent and full of ambition to become thoroughly equipped in all that pertains to a high order of nursing"

THE VALUE OF IODOFORM IN SURGERY

The year 1887 was prolific of iodoform literature, probably the more so because of the paper of Heyn and Rovsing, of Copenhagen, that appeared early in the year, and in which the surgical value of iodoform was denied The latest contributions to the subject are the papers of A Kunz (Ueber die Wirkung des Iodoforms auf Infectionsorganismen, in Ziegler and Nauwerck's Beitrage zur pathologischen Anatomie und Physiologie, Bd ii, Hft 2, Sanger (Ueber die Einwirkung des Iodoforms auf das Wachs thum und die Virulenz der Milzbrand-bacillen, Deutsche medicinische Wochenschrift, No 33, 1887), and Jeffries, of Boston (Anti-bacterial Action of Iodoform, American Journal of the Medical Sciences, January, 1888)

The papers of Kunz and Jeffries contain reviews of a number of bacteriological experiments are also interesting, as showing how bacteriological work is to be done, how evidence is to be weighed in this kind of work, and how clinical deductions are to be made Jeffries asserts that the experi ments of Heyn and Rovsing were free from errors of method, and were made in accordance with accepted rules In fact, the objections made to the experiments were, that laboratory tests are no evidence of what occurs in the body, that in these tests no iodine, by virtue of which iodoform acts, was set free "Strangely enough," says Jeffnes, "none have pointed out that the experiments only disprove a germicidal action, but do not exclude an inhibitory action on their growth The injurious effects of crowding are so great, in solid cultures, as soon to cover up any slight inhibitory action of the 10doform " The two most important points in Sanger's paper are that the presence of non-growing anthrax bacilli causes gelatine tubes to dissolve, and that 10doform limits the growth of the anthrax bacillus, and prevents its taking in a re inoculation

Until Kunz and Jeffries entered the field the whole question of the value of iodoform was in-The early writers noted that the volved in a mist drug had a distinct action on putrefaction, but the more recent writers failed to observe any action on pus-producing bacteria, while the majority of clinicians were decidedly in favor of the drug clusions of Kunz and Jeffries should have a direct It is evident tendency to settle the vexed question that clinical experience and laboratory experiments should lead to the same conclusions, else one or After his numerous experiboth must be wrong ments and somewhat exhaustive review of the literature of the subject, Kunz contents himself with the conclusions that iodoform will prevent septic intoxi-The conclusions of cation, but not septic infection Jeffries are of more practical value to the surgeon, for the reason that they tell more

- I Iodoform not being a germicide is not a fit substance to use to procure asepsis of instruments, materials, or wounds
- 2 Iodoform is allowable, with the present state of our pharmacopæia, in infected wounds where the true germicides are contraindicated, as by danger of poisoning or impracticability
- 3 As has long been known, iodoform has a decided tendency to stop serous oozing, and, therefore, may be indicated in wounds where the moisture threatens the integrity of the aseptic or antiseptic dressing

THE MEDICAL DIVISION OF THE PENSION

Bills have been introduced in the House of Representatives at Washington, proposing to increase the efficiency of the Pension Bureau by adding one surgeon and six medical examiners to the present force This would make the medical staff of the Pension Office consist of one medical referee, one assistant medical referee, three surgeons and twenty-four medical examiners, which would certainly seem to be as small a medical corps as could be reasonably expected to properly examine and supervise the immense number of pension applications that reach the Pension Bureau of this nation in these days bills also propose to increase the salary of the medical referee to \$4,000 per annum, that of the assistant medical referee to \$3,600, that of the three surgeons to \$3,000, and that of the medical exammers to \$2,500 These propositions, both to increase the number of members of the medical staff of the Pension Bureau, and to increase their salaries, should be adopted without opposition from any one, for the proper discharge of the duties required demands thoroughly qualified medical men, and such cannot certainly afford to accept those positions for less pay

SOCIETY PROCEEDINGS.

SUFFOLK DISTRICT MEDICAL SOCIETY Stated Meeting, January 11, 1888 SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

THE PRESIDENT IN THE CHAIR Dr. W N Bullard read a paper on A CASE OF CEREBRAL LOCALIZATION WITH DOUBLE TREPHINING

(See page 228)

DR J J PUTNAM said Cases of brain operation are rare, and we should learn from them all we possibly can Although as Dr Bullard has said, we can through our knowledge of certain portions of the brain, localize with considerable accuracy certain lesions, especially those involving the motor functions, it is, on the other hand, I think, very difficult to tell what the nature of the lesson is, and the exact relation of the disease to the symptoms difficulty of determining at what depth a tumor lies, the fact that tumors which grow very slowly so often occur almost without symptoms, and our ignorance of many of the conditions that govern the occurrence

although the case before us is highly interesting and justified. Dr Bullard's claim in regard to it, that the diagnosis as to the lesion was made during life, it cannot count as one where much benefit could have been hoped for In these congenital troubles, I don't see how we can expect to produce a result that would be particularly favorable unless we can operate upon them very early And then the trouble comes in that the difficulties of early localization are greater than at a later time The rapidly developing brain of the child is so susceptible to permanent injury, its growth is likely to be retarded, and an atrophy involving not only the seat of the lesion, but that of the whole hemisphere of the brain is liable to follow from any injury received at birth, or in the very early years of life Moreover, the fact that localized lesions, even if they might have been removed soon after they occurred, give rise to secondary changes not only in the hemispheres of the brain, but in the deeper lying tracts, would, it seems to me, render this class of cases not a favora-

ble one for operations of this kind

In regard to the operation itself, of course the points are many and interesting, and I would not attempt to touch upon them at any length mark made in connection with a case operated upon in New York struck me as significant. It is important that the opening in the skull should be large, that quite a window should be cut, instead of the ordinary trephine hole, the belief being that under those circumstances the brain is less liable to protrude from the opening, and that the wound is more likely to heal favorably I recently saw a specimen from a case in New York, which unfortunately termmated unfavorably, where, although no suppuration had taken place and no sign of septic poisoning showed in life, the patient died from what was considered as red softening, immediately beneath the seat of the operation without it being possible to discover any cause for it The brain simply became softened, that was all one could say about it has usually been considered that serious results from operations are not likely to occur Dr Spitzka, in experiments on animals, has gone further than that, and says that not only are unfavorable results not likely to occur, but a second operation in the same region is even less likely to do harm

I cannot help saying a word about a case that I saw myself, which seems at once an illustration of the difficulties in the way of the diagnosis of cerebral tumors, and also of the possibilities of cerebral sur-It was the case of a woman that exhibited through life no localizing signs except toward the end of her life a slight facial paralysis on one side yond that she had an intense headache, and a progressive stupor She died, and at the autopsy a large sarcomatous tumor was found pressing apart the sides of the fissure of Sylvius, having caused no real injury beyond the pressure, to the brain itself. and being attached to the dura mater on the sphenoid bone with very slight attachments If the tumor of symptoms, would seem, I think, to make us very could have been reached it certainly could have properly cautious in raising any very sanguine ex-been removed without injury, I think On the pectations about the result in most cases And other hand, it had grown to the size of one-half or two-thirds of one's fist, without it being possible to diagnose it as central or cortical

DR MORTON PRINCE said In regard to the possibilities of the operation, I feel like being a little cautious, as if we must not go ahead too fast don't yet quite know what the possibilities of brain surgery are There are certain fixed principles upon which, in the light of our present knowledge, brain surgery must be based These are that an operation should be undertaken only for the removal of a lesion causing symptoms of irritation, or threatening the life of the patient All operations thus far have A brief survey of been based upon this principal these cases will make this clear Up to this time they have been reported only fifteen cases of pure Of these, eight were cases of tumor, of which only three survived the operation, and of these three one died later from recurrence of the In the remaining seven cases, the operation was undertaken for the removal of a supposed lesion causing epileptic fits, in these seven cases there was recovery from the operation itself. It is interesting to note that the operator in these latter cases as well as in the successful cases of tumor was Victor Horsley, who is the only operator, I believe in whose hands the operation has not ended fatally He has operated nine times with only two deaths In one of his cases only was death the immediate result of the operation, and in this case it should be said that the patient was in a very critical condition fied at his success in localization in this case when the operation was undertaken The second death (the one just referred to) was due to recurrence of the tumor In the seven cases operated upon for epilepsy due to irritative lesion, there was complete and permanent cessation of the fits in four cases, and more or less improvement in three In this latter class of cases the operation was undertaken with the idea as of removing the diseased tissue which was regarded the point of irritation and the exciting cause of the fits Now it will be seen that the principle underlying all these operations was that there was a lesion of the brain, causing not merely paralysis and loss of function, but aggravating irritative symptoms, or else threatening life one case the fits aggregated three thousand in two To operate upon the brain in such cases as these I believe to be sound surgery and sound neurology, and there seems to be a legitimate, even if limited field in this direction, and perhaps a brilli-Time, however, can only settle this ant future But when we go from this to cases of paralysis, and that too with spastic symptoms, I confess I feel very doubtful I am unable to see on what sound principle of neurology, operation in such cases can be I am unable to understand how a pure paralysis due to a hole in the brain is going to be improved by making the hole bigger All that we could do by operation would be to cut out more brain, and that is equivalent to enlarging the lesion, and would simply increase the extent of paralysis Furthermore, when spastic symptoms of long standexists secondary degeneration extending down along indication for interference, and that is in hæmorthe direct fibres through the motor tract to the cord, rhages from fracture. In a diagram in which the

and it is to this secondary degeneration that the spastic condition is due Mere removal of the cortex could not then in any way relieve these symptoms

There is one point of which the reader spoke and which I think should be emphasized still more, and that is the necessity, if you are going to operate, of taking into account only the symptoms themselves in localizing the lesion That is, the proper localization depends entirely upon the grouping of symptoms, and it is only by such grouping that we can localize the disease It makes no difference where the original injury to the skull is situated, and this This seems a trite reshould not be considered I rememmark, and yet I think it not uncalled for ber seeing a case the other day, a case of aphasia, where the trephining was done on the top of the head, attention being directed to that spot on account of a former accident Of course the lesion must have been lower down

Perhaps there is another class of cases where there is a possible field for this operation, and that is where, in cases of this kind, there is not only paralysis of one or more members, but where there is also athetosis or clonic localized spasms of severe type I saw a case of this kind some time ago I suggusted the operation, but did not see the patient again I think perhaps in that case something might have been done I do not say this to criticise the paper, for I think the reader should be highly grati-

I have very little to Dr J Collins Warren say, but have studied this matter up a little I was struck by what was said about the caution with which we should go ahead in this region of surgery think that corresponds pretty well with the writers on this subject, especially in works on surgery They say that the study of the cerebral topography, and the physiological action of these centres indicates rather what not to do than what to do say, the opportunities for interfering and trephining are comparatively few as compared with the indications when we should abstain, and yet many of these indications might tempt one, ignorant of cerebral topography, to interfere and relieve pressure or something else there For instance, if we have injury with symptoms of paralysis, which correspond to that tract, not too extensive, that might perhaps be a reason for interference If, for instance, after a blow, we have paralysis of the arm and leg, that might be an indication for trephining at the upper But if we have portion of the fissure of Rolando total anæsthesia, not only is the motor tract involved, but an indefinite amount of brain convolution behind the ascending parietal That is, it is an unknown quantity, a considerable surface, so that in order to reach that surface we would have to put on four or five trephines side by side, in order to uncover it and relieve it. There it would be contraindicated Limited paralysis or anæsthesias, with well defined injuries, give the indications for interference in a surgical case

From the surgeon's point of view there is one other

the exact point crossing the middle meningeal artery, that point, and get at the artery comparatively near put the trephine on the same horizontal line but rior, in some cases The reported cases are, I think, else a considerable number, although I cannot quote them

Dr Prince spoke as if trephining for epilepsy were I think that it is an opercomparatively a novelty ation that has been done considerably, although perhaps done in a different way, such as trephining for simple and depressed fractures, I would like to ask if there is any special localization, other than the determination of the seat of the depressed fracture?

I referred to a different form of DR PRINCE Not merely trephining, but removing a to suppose that there is a gross lesion Hughlings Tackson has suggested that in cases of epilepsy and the beginning of the convulsion to a focal point in centre as the focus of the epileptic discharge the thumb, and to progress in a definite order throughout the body, in that case the centre for the thumb will be found to be the seat of the most intense dis- lowing charge, and he considers it good neurology and surgery to remove this centre Acting upon that advice, Dr Horsley, in one of his cases, did remove the centre for the thumb, with the result that he cured It is in that sense that I speak of brain surgery as being a novelty, and it is in this field that perhaps there is a considerable opening for the future

DR S H WEEKS, of Portland, said

If I may judge from my own experience and observation, the operation of trephining the skull is not attended with as much danger as is supposed recall a case (and I wish I could detail it more acmonths ago, in a young man who was having epileplowing an injury which he received when a lad, some the benefit would be much greater fourteen or fifteen years ago He was riding a horse for raking hay, and was suddenly thrown from the horse, and as the rake revolved one of the teeth, made of steel, struck his head near the bregma and discussion I think a little to the right of the median line with depression moved some portions of the skull

middle meningeal artery is represented, we can see but I hope some time to report the case, that you how, by measuring back from the external angular may have the exact measurements and symptoms, process three and one half centimetres, we can strike and derive more advantage than from any recital here now I am sure that the convulsions first started and if we were to have symptoms of pressure in that in the hand, and then extended into the arm, and part of the brain substance, for instance, of facial then involved the entire side. He had been at the paralysis, we could readily interfere, and trephine at hospital once before, and after consultation we refused to operate He went home and suffered an-If we found that there was any difficulty other year, and his convulsions becoming very freat that point, but it appeared that there had been a quent, he again returned, and said "If there is anyhæmorrhage from the artery, the indications are to thing that you can do, I want it done, no matter what the risks or dangers are " At the second conmore posteriorly, because the blood clot may be in sultation we decided to operate I repeat this more the posterior part of the brain rather than the ante- to show the safety of the operation than anything Making an incision through the skin, I found that there was a portion of the skull that had not been restored, and here the scalp and dura mater were adherent I dissected off the scalp from the dura mater, directing my dissection as well as I could so as not to open into the cavity of the arachnoid, and came to the edge of the bone, which seemed to be indented, and then took out a section of bone Not finding a depression there, I felt that I had not reached the difficulty, and took out another portion, and upon that button there was an exostosis from portion of the brain, even when there is no reason the inner surface to the extent of three or four lines, extending down on to the dura mater and firmly ad-After I had loosened the segment of herent to it epileptiform convulsions, where you are able to trace bone, finding this projection adherent, I was obliged to take out an elliptical portion of the dura mater in the cortex, it would be justifiable to remove that order to remove the bone. I brought the edges of the dura mater together with small catgut suture. example, suppose the convulsion always to begin in and then closed the external wound, applied a simple dressing, and put the patient to bed

There were almost no unpleasant symptoms fol-In fact, so comfortable was he after the operation, that he would sit up in bed in spite of my cautions, and declared that the only thing that he was kept in the hospital for was to let his hair grow I believe the danger in trephining is not as great as we have supposed And while there are many diseases that we may not be able to cure by brain surgery, yet I believe there are many cases which are capable of cure, or of being benefited by these operations One word in reference to the future of this patient While the fits were not cured, they were very much mitigated I saw him a few weeks ago and inquired particularly for the sympcurately than I am able to), that I operated upon at toms, and he said that once a month or so he would the Maine General Hospital some year or eighteen have a slight convulsion, but nothing to compare with what they were before, and were it not for his tic fits every week, and sometimes twice a week, fol-intemperate habits, which he continues, I believe There are other cases that I think of, but I will not relate them thank you for your courtesy and kindness, and shall be very much interested in listening to the further

DR P C KNAPP said I have been very much the time there was a compound comminuted fracture interested in the paper as showing the very exact lo-The physicians at the time re-calization of the lesion I would agree with Dr The wound Putnam and Dr Prince in what they have said healed, leaving a cicatri, and in the course of a year There is one point, however, that seems worthy of or two there commenced convulsions, first in one notice, and that is the fact that although there was hand, and I am sorry that I am not able to say which, apparently a lesion in the cortex, which is so common in these cases, there were no convulsions at there was no disease whatever, where there was any time in the history A year and a half ago Dr Sachs, of New York, laid special stress upon the presence or absence of convulsions as an important one he removed not only the tumor, but also the symptom in the localization of the lesion of intra-cerebral hæmorrhage or embolism, he be- lesion lieved that there were no convulsions, but in cases where there was cortical disease, he believed that report, when he came to open the skull he found no convulsions were present

This case, I think, is of special interest, as showing the presence of probable cortical disease and entire absence of convulsions I would say, moreover, that as the case was reported, I do not see what justification there was for either operation Certainly the cica-'trix on the right side caused no symptoms, and after so long a duration there was no evidence of any disease there to be operated upon Nor do I see what could have been gained in any way by operating upon the reported in which there was no gross lesion other side, for the symptoms were those merely of paralysis and secondary degeneration, and no operation the different functions of the brain, I recall a case whatever could have helped the patient

I agree with Dr Prince fully that, in case of convulsions or athetosis, perhaps there might be benefit in removing portions of the brain substance, but certainly there is one point that might have a bearing in such cases In some cases that I have seen, where the limb was only partially paralyzed, there were loss of the power of speech. It was at the time athetosis or convulsions starting in the hand Here, if you were to cut out the centre for the hand, which was the chief seat of the lesion, you would produce absolute paralysis of the hand, this would deprive the child of a fairly useful hand, and would leave him in a less advantageous position for getting through the world than he was in before

Of course, in localization we refer interest DR PUTNAM chiefly to cortical localization It seems to me, however, that this case is one where localization of that found the dura mater at that point a good deal conkind is really not possible. What we had present was a hemiplegia, apart from the secondary changes The aphasia, I take it, would count for little or nothing, for the child had never spoken Even if that were not so, the function of speech would be probably sooner lost in a child's brain than in an adult's, so I cannot see how we could strictly localize the It was evident that it involved structures either so extensive or so far beneath the surface as to include all the tracts coming from the opposite theory of the localization of the seat of language side of the body, that is to say, it must have been a very extensive cortical lesion, and in that case not strictly localizable, or else a moderately deep-seated injury, and I do not see how it would be possible to localize it with certainty in one part rather than another of the motor tract, except that we might per- fracture or other injury, has so great a future as, perhaps say that it was not in the pons

I would like to ask Dr Prince one DR KNAPP portions of the cerebral cortex where the convulsions always began in one portion of the body, he said that Hughlings Jackson advised it whether he recalls any case in which Mr Horsley about decided pressure symptoms, in which we feel operated where there was no gross lesion of the brain? It seems to me that in every case he found some there are certain localized abscesses which can be thickening of the meninges, or a tumor, or some-operated upon with advantage All these lesions thing of the sort I do not recall any case where must be decidedly near or at the cortex, or we are

simply the functional disease starting at that point

DR PRINCE There were, I think, two cases In In cases | thumb-centre In this case he diagnosed a doubtful He knew that there was a lesion, but was in doubt as to its exact nature As I understood the lesson whatsoever, but he still removed the portion of the brain corresponding to the seat of the epilepsy At any rate, Jackson advised it, and said that he would advise the operation in the future It seems to me that this is a sound principle to go upon simply as a theory in a very grave case Of course you would not operate upon a case of that kind unless it were a case that justified some risk

> I did not know that a case had been Dr Knapp

DR WEEKS In speaking of the localization of that came under my observation several years ago, where a man who had organic disease of the heart was taken suddenly with aphasia, and the sickness lasted only two or three weeks His sickness increased day by day, manifesting decidedly cerebral The most prominent symptom was the symptoms when the discussion as to the seat of language was going on in the medical journals and societies, and when the medical opinion was not as well satisfied as now in regard to the localization, and yet my attention had been called to the anterior portion of the left hemisphere, the temporal lobe, as the seat of language, and I watched the case with a good deal of When he died, I was successful enough to get an autopsy and, on taking off the calvarium, I gested, and on opening through the membrane, and going through a very thin portion of the cortical substance of the brain, I came to a large abscess Now I believe that to-day, if you had such a case as that, you would operate upon the abscess and give exit to the pus, and in such a case as that I believe you would save the life of the patient Here was the seat of the lesion, and, so far as any case can prove the theory, certainly this goes to substantiate the

I am quite agreed as to the impor-Dr Walton tance of the surgeon's being prepared for early operative interference in just the cases that are indicated I do not think, however, that this variety of cerebral surgery, where the healthy skull is trephined without haps, was hoped for it at first, certainly no such future as abdominal surgery, for the cases are really In speaking of Mr Horsley's removing limited in which the operation is sufficiently indicated I agree with Dr Prince that, as we eliminate the cases, we shall finally become pretty well sifted down I would like to know to lesions that are irritant, and lesions that bring pretty certain that we can relieve pressure

not justified in operating there will be so few cases in which we will feel ourselves justified in operating, that opportunities will be rather rare We have been on the lookout at the Massachusetts General Hospital for an acceptable case, and I fancy it has been true at the other hospitals, and there has not been, so far as I know, any case admitted The nearest we have come to it was one case in which we did diagnosticate a tumor in the cortex There was paralysis or partial paralysis and, if I remember rightly, convulsions of one arm, in which we were sure that the tumor was at the cortex, and advised operation, but the patient demurred

I was interested to hear Dr Putnam speak of a considerable opening in the skull. I think it is important to make as large an opening as possible, not only for the sake of after-results, as far as the case 15 surgically concerned, but also for the sake of helping us to localize My attention was particularly brought to that point by going to the demonstration of Drs Warren and Richardson, last evening, in which the skull was trephined on the cadaver and the fissure of The fissure was localized according Rolando found to the regular method, the opening made perhaps three-quarters of an inch in diameter, and directly in the middle of the opening was a fissure, but it seemed to me at almost right angles with the direction one would suppose it to go But, on removing the calvarium and dura mater, it was afterwards discovered that it was the fissure of Rolando, but it had taken a turn at that point It is not always so easy, even after the brain is removed, to determine just where the various fissures are, as sometimes those fissures which should be the most distinctly marked are the least so, and other less important fissures become more marked And in this case I should say that the frontal fissure was much more marked than the fissure of Rolando

Dr Bradford I did not have the pleasure of hearing Dr Bullard's paper, but he has allowed me to read it and I think it covers the ground pretty thoroughly It only remains for me to say what the reasons were for performing the operation I think some apology should be made for an attempt at an operation on a child who was idiotic The oper ation was done in this case chiefly for the reason that it was hoped that the spastic symptoms might be re-The parents were told distinctly that it was lowing the operation lieved purely experimental surgery, and they wanted to have the operation done, even on those grounds withstanding that, in these cases of spastic paralysis, the cortical substance is in a large number of cases involved, it was hoped that possibly some irritative centre might be found, and the removal of that might relieve the spastic paralysis of the leg and arm, and render the locomotion of the child better The result proved that the operative interference was not justified except as an experiment The cause of death in this case is, I think, somewhat interesting The child died, unquestionably, of shock, and the question arises whether the double trephining may

The result will be, that better to have trephined in one locality, and waited before trephining in the other It did not seem so at the time, and the double trephining was undertaken, trephining over the cicatrix to satisfy the parents, who believed that the condition was in some way due to the depression of bone Both Dr Bullard and I thought not That double trephining may have given rise to the shock

Another cause of death may have been the use of morphia before the operation The child was given morphia subcutaneously or by the mouth a short time before the operation, carrying out Mr Horsley's idea for the purpose of contracting the vessels in the I think a larger dose was given than would have been needed, 12 of a grain was given, and I think $\frac{1}{20}$ would have been better At any rate, during the etherization the child was more or less under the influence of the narcotic That may have acted injuriously, although the child came out from the ether and morphia before dying

Another cause which may have given rise to death was bleeding from one of the larger vessels in the diplæ during the operation That was plugged by a piece of wood, but the child lost some blood think, so far as we can judge from the single case, it would not be desirable to do a double trephining in a child

Dr M H RICHARDSON said It seems to me, as Dr Walton has said, that the probable future of cerebral surgery does not promise the results that we get in other parts of the body, the peritoneal cavity for instance My own experience in trephining for the sake of finding an abscess, for removing a possible irritating cause of epilepsy, has been uniformly unsuccessful I reported two cases a year ago of trephining for epilepsy, and another for cerebral symptoms after compound fracture, without any benefit whatever And since then I have trephined to evacuate a probable abscess after a gunshot wound, a good case for symptoms arising after injury In the latter case death followed, and in the first two cases there was no benefit whatever It seems to me in a certain number of cases, where symptoms of definite localized irritation can be made out, at present it is the duty of the surgeon to interfere on the chance of doing some good But it seems to me that, as matters now stand, the chances are that in a large number of cases there will be no permanent benefit fol-

Dr Bullard I agree entirely with Dr Prince and Dr Putnam in regard to the fact that we should not be too fast in brain surgery I think that nobody who has had anything to do with the localization of lesions fails to understand the difficulties and the many problems we have to consider, and the very small number of cases in which we are justified in operating But it does seem to me that such a class of cases exists, and although the most prominent cases are those where convulsions or irritant symptoms follow, yet we must not limit ourselves to them entirely Ross says that the larger number of hemiplegic cases and convulsions come on at least by the not have been more than was proper to have done time the child has reached 8 years, or sometimes a It is a question whether it might not have been little later. I have not experience enough to know whether that is true, but it is certainly true that, in a contented, and went to sleep in about an hour certain number of cases of spastic hemiplegia, the convulsions do come on later Now I should be very slow to advocate operation in cases of spastic hemiplegia unless there were some special reason for doing so beyond the mere fact of the existence of a hemiplegia, but I believe that there may be certain cases where it would be advisable to perform the In this particular case I think we had good ground for localizing the lesion as we did course I have not gone into all the details A good many symptoms were absent which would have been likely to be present if the lesion had been in other Of course, in such a case, the parts of the brain operation is done with the understanding that it can only be experimental

DR BRADFORD The sense of the meeting seems to be in disparagement of cerebral surgery think we shall put ourselves in the line of modern surgery if we take the ground that cerebral surgery has not a future, and I think we can anticipate a brilliant future for it We are only in the beginning and I think what has been done shows that there is a great deal more to gain when our experience is greater I think it is in the recollection of most of us here, that here in Boston the statement was made on the best urethral caruncles were removed, and a uterine case, surgical authority, that ovariotomy was not a justi-We have lived to see that dictum fiable operation not accepted, and I think we will find that cerebral minims surgery has a future before it that we have not yet in a case of chronic nephritis with insomnia. A pathought of

DR GEORGE B SHATTUCK then reported some

cases of Family Ataxia

DR FRANCIS H WILLIAMS exhibited the new drug,

AMYLEN-HYDRATE

and he said This substance may be used a a substitute for chloral It has a peculiar odor, something like ether, and the taste is camphor-like, with an after-taste of peppermint It is a clear limpid liquid, and is fairly soluble in water It takes about eight parts of water to dissolve one of the drug, and is quite soluble in alcohol drachm to a drachm, 3 to 5 c c It does not act so strongly as chloral, it is not so powerful a drug, but on the other hand it is free from some of the dangers It does not act to depress the heart and respiratory centre as much as chloral does, and for In many cases it that reason is a safer drug to use seems to work well, in a smaller number it has not In one case for example, in been very efficacious Dr Mason's service, 40 minims of the drug were used in a uterine case where the patient had slept very poorly for several nights She had some pain One-sixth of a grain of morphia, repeated, was not able to give her the required sleep This new remedy most was the remarkable absence of after-effects after was given at 10 o'clock and she slept nearly all night As a rule the aftereffects are not unpleasant Here and there a few inconveniences are experienced from it In one or perienced a pleasant sensation for an hour as though paraldehyde, and the eructations that rise after its two cases the remark was made that the patient exdrunk, and was somewhat silly In this case she felt use and the very great difficulty of mingling it pleas-

will not do more than call your attention to the drug and suggest that for certain cases it is likely to be a valuable substitute for chloral, but a better reason for not saying more about it is that perhaps Dr Mason will be kind enough to tell us something of his experience in using the drug. I have reports of cases in which it has been used in Germany, and in about 80 per cent of the cases it has proved satisfactory Unpleasant after-effects have not been noticeable

DR A L MASON said I have a brief memorandum of some of the cases, but I will not delay you with it at present except to say that they were all cases of marked insomnia There were two cases of rheumatic fever, with heart complications, in which we obtained four hours' sleep In one case of severe measles four nights of uninterrupted sleep were obtained One restless typhoid patient was not quieted by urethan, chloral, bromides or opium Drachm doses of amylen-hydrate gave a good night's sleep A case of acute tonsillitis, sleepless for four nights, and another patient with dyspnœa, slept well after half a drachm A case of abortion obtained good sleep for five nights

Another patient who had sleepless nights after in which one-sixth of a grain of morphia, repeated, was of no avail, had a good night's sleep after 40 And the same dose answered the purpose tient with cardiac insomnia, who had been treated with everything else, has had from five to seven hour's sleep after this drug It effect appears better than It seems to be free that of paraldehyde or urethan from the disagreeable after-effects of chloral or opium The sleep usually comes within twenty minutes after it is given No ill effects were observed There was mild intoxication in a few instances

These cases are, of course, too few in number to draw conclusions from them as to the power of this drug I believe it is not yet in our market and probably Dr Williams has had the only specimen

DR ALBERT N BLODGETT If it is in order I would The dose is from half a like to say a word for paraldehyde that has been mentioned in connection with the new drug presented to-night, and which has previous to this seemed to be the drug which has produced better results than any other of that character Of course, when I say "of that character," I mean a drug which is a simple hypnotic and not a sedative like opium Paraldehyde has on several occasions, under my observation, produced a sleep which seemed to me more restful than that produced by any other hypnotic except perhaps urethan, and the latter seems to me less efficient, as it soon loses its influence, whereas paraldehyde seemed not to lose its efficiency What pleased me At 10 15 she was asleep, paraldehyde, which has been mentioned as pertaining That seems to me to be an also to this new drug important advantage for we don't know how long it may be necessary to use it, and the use of other drugs might not be desirable. The nauseous taste of antly with other substances, are serious objections to

its employment

DR WILLIAMS This new drug does not seem to me to be as disagreeable to take as paraldehyde That is one advantage that it has, and I think it is a rather stronger drug

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, February 2, 1888 THE PRESIDENT, T M DRYSDALE, MD, IN THE

DR B F BAER presented the specimen and read the report of a

CASE OF NON-PAPILLARY INTRA-LIGAMENTOUS CYST, ENUCLEATION OF ENTIRE TUMOR IN THE RIGHT BROAD LIGAMENT, OF LINING MEMBRANE ONLY IN THE LEFT

Sessile tumors, whether cystic or solid, are always more or less dreaded by the operator because of the greater difficulty and danger attending their removal, and also because, in the case of sessile cysts, the results as to the permanent relief of the patient is less the vagina, which would afford her great relief certain than where the tumor has a pedicle ically and pathologically, therefore, these cases are of great interest and importance

Pain and hæmorrhage, are the important subjective symptoms The former is usually present, sometimes in great severity, the latter is at times alarming in the quantity of blood lost and in the frequency of This is not surprising when we conits recurrence sider the close relation which these tumors sustain to the uterus and to the otner pelvic organs and tissues The wedging and pressure which results from the left ovarian region growth of the tumor in the limited space produce great congestion of the blood-vessels from stasis. The uterus becomes enlarged and softened in consequence and metrorrhagia follows, but the hæmorrhage is conservative to a certain degree in relieving the distended vessels, probably averting rupture of a vein in the broad ligament or in the tumor pain which results from the stretching of the nerves involved is also relieved or modified by the depletion following a free hæmorrhage from the womb the conservative line, it sometimes becomes uncontrollable and results in acute and serious anæmia.

the hilum of the ovary or from the Wolffian relics in the broad ligament are usually papillomatous, but that non-papillomatous sessile cysts infiltrating the broad ligament are not infrequently met with is shown by the following statement from that author be ascertained, none of these contained glandular wedge between them

matous growths, the result possibly of stray Wolffian relics I have presented at least one such specimen to this Society, and I have seen others On the other hand the multilocular ovarian cyst without papillomatous material has been found, in rare instances, to have invaded the hilum and broad ligament in its Doran records two such cases He says, I have seen two cases where a sessile cystic tumor of the ovary was removed, and this proved to be an undoubted case of glandular cystic disease invading the hilum and broad ligament "

The case which I here report is probably another

instance of this pathological anomally

Mrs J was sent to me by Dr O H Adams, and entered my private hospital in April, 1887 She is 32 years of age, married, and has had three children, the last two (twins) eight years ago Following her last labor she had puerperal mania, which necessitated her confinement in an insane asylum during Four years ago she began to have four months attacks of sharp pain in the right ovarian region, radiating to the groin and down the anterior portion of the thigh The pain was intermittent in character and cramp-like, lasting hours at a time, and was usually followed by a purulent, fetid discharge from other times the attack would end with a profuse metrorrhagia, which would leave her pale and weak, but free from pain About two years before coming under my care, she first noticed a "lump" in the right groin which has gradually increased in size time after she noticed a similar growth above the left groin She was considerably emaciated and looked very ill

Examination revealed a tumor as large as a child's head in the right iliac region and a smaller one in the The tumors seemed to be fixed in the pelvis and to have a broad base attachment They were immovable below but mobile above, and semi-fluctuating Vaginal examination showed them to be so deeply attached in the pelvis and so intimately related to the uterus that I was unable to complete my diagnosis without anæsthesia patient was therefore placed in bed and ether administered, when it was found that the uterus was elevated by the tumor on the right side, with which it was connected There was evident fluctuation though the the flow once started does not always remain within tumor was thick-walled and very firm, almost hard The lower surface occupied the position of the broad ligament at the side of the uterus The same condi-According to Doran, sessile cysts which arise from tion existed at the left side, but to a less degree diagnosticated sessile cystic disease of both ovariesor broad ligaments, and advised immediate operation.

to which the patient gladly consented

On April 13, 1887, I proceeded to operate, being kindly assisted by my friend, Dr Daniel Longaker "In 24 cases where I assisted at the operation, sessile | When the tumors were exposed they were found to cysts infiltrating the broad ligament were removed, be so closely connected with the womb that they more or less completely, but their origin could not seemed to be one with that organ, which rested as a The Fallopian tubes exgrowths, most were multilocular, but papillomatous tended outward over the upper surface of the tumors, growths did not exist " (Tumors of the Ovary, etc., while the broad ligaments and the greatly distended p 68) Further the ordinary pedunculated multiloveins of the pam piniform plexuses were expanded cular cyst of the ovary sometimes contain papillo so as to apparently envelop them, the whole presenting a dark purple appearance, which was not at all After separating some slight adhesions on the posterior aspect of the larger tumor, and rolling it forward, the nacreon surface common to the multilocular ovarian cyst was exposed to view lecting a spot on this free surface because it was less vascular, I now plunged a trocar into it, when about two pints of a tarry-looking fluid drained away more thorough investigation which the diminished size of the tumor now afforded, showed it to be adherent to the cacum also Previous to beginning the enucleation, I passed a long blunt needle charged with a double ligature through the expanded broad ligament at its least vascular portion between the uterus and the tumor, and as far below the Fallopian tube as could be done with safety side of the ligature was then drawn up and tied close to the uterus, including within its grasp the tube and Thus insured against hæmorrhage from that source, I now cut through as far as the ligation extended, and continued the enucleation down to the base of the tumor, and then outwards, finally separating it from the head of the colon was some bleeding from the numerous veins which were broken, but this was readily controlled by catch- ran diagonally towards the splenic region. It entered forceps and ligatures

Attention was now given to the tumor on the left This was found to be deeply imbedded in the pelvis and firmly fixed to the uterus, Fallopian tube, descending colon and rectum The upper surface was covered with a net-work of distended veins, some of them as large as a quill Enucleation of this tumor seemed too hazardous and hysterectomy was out of the question, for to do the latter the tumor must first be dissected from the colon and the pelvic floor, which was not practicable I determined, therefore, to evacuate the contents of the cyst by aspiration, and then to shell out the lining membrane, or, failing in this to insert a drainage tube But while endeavoring to find a position for puncture my finger passed into the tumor, low down on the posterior border of the broad ligament Instantly the parts were flooded with a tar-like, semi- peared, apparently by being incorporated with the fluid substance similar to that which had been tumor and by having its connective tissue and fat reevacuated from the cyst on the right side removed as quickly as possible by sponging I then passed my finger through the opening which I had large bundles, and had all to be ligated thus accidentally made, and after a careful and gen- the tumor had evidently been mourished, for what tle dissection succeeded in removing the entire looked like a pedicle was slender, long and twisted Blood was now flowsecreting surface of the cyst ing from the small valvular opening in the broad Goodell did not dare follow it up to its source ligament, but as it was apparently venous I hoped diagnosis had been sarcoma of the omentum, but he to check it by compressing the now flaccid folds of was so uncertain of it that he sent the specimen to the broad ligament, for this purpose several large Dr Formad, who pronounced it a leukæmic spleen sponges were inserted and external pressure made It weighed not quite 6 lbs upon them while the abdominal sutures were being four days, then symptoms of embolism set in, the The sponges were then removed was still a slight flow of blood, but as it was doubt- the sixth day less only a venous oozing I concluded to close the ature on the subject, his case was the eighteenth in wound and trust to pressure and the drainage tube The patient was placed in bed and the tube care- all had died save one fully watched During the next two or three hours several teaspoonfuls of quite bloody serum passed operation for removal of a leukæmic spleen spoken through it, after forty-eight hours the tube was re- of by Dr Goodell had occurred under Dr Franzomoved

This patient made a slow, but good recovery, and went home six weeks after the operation She has been entirely relieved of her former sufferings, and the loss of weight and strength have been regained

DR WM GOODELL reported

A CASE OF SPLENECTOMY

Mrs R, æt 40, had chills and fever in early life. but after her marriage eighteen years ago she removed to a healthy country town and had no return She has had two children, the youngof the disease est seven years ago At this labor she had a serious flooding and was confined to her bed for six months from excessive prostration Since that time she has never been well, being weak and miserable Her monthly periods were always free and generally pain-Last March she had a very severe attack of what her physician called malarial fever, and her life was threatened by repeated attacks of hæmatemesis and hæmoptysis A sore tumor was now discovered, which was pronounced to be a uterine fibroid, and she was sent to Dr Goodell He found the womb pushed low down and retroverted by a solid tumor, which started from the region of the right ovary and the pelvis so low down as to cause bulging of the an-The womb seemed to be terior wall of the vagina independent of the tumor, for the former could be moved about freely with the sound, yet when the tumor was pressed upwards it conveyed motion to the womb, drawing it also upwards The tumor was never free from pain and the complexion of the woman was markedly cachectic The diagnosis was made of sarcoma either of the right ovary or of the omentum

At the operation very long incisions were needed, reaching not quite up to the ensiform cartilage tumor was of a dark purple color and was attached in every direction by very long, tortuous and wholly denuded vessels, which looked like the largest earth-Most of the worms and were of analogous length vessels came from the omentum, which had disap-This was moved by absorption, leaving the blood-vessels bare These vessels were either single or else grouped in By them It was lost in such a mass of livid veins that Dr The woman did well for There sputa became streaked with blood, and she died on So far as he can learn from the literwhich a leukæmic spleen had been extirpated, and

DR HARRIS said that the case of recovery after

The proporlini, of Medina, in Northeastern Italy tion of leucocytes was small and probably accounted for the recovery of the patient been made before the operation

DR Parrish had a few years ago seen a case of the late Dr Wallace's, in which a diagnosis of fibroid of the uterus had been made A tumor the size of the two fists was found near the side of the uterus The patient developed peritonitis and was tapped by the assistant physician, some dark fluid was with-Death took place a few months after, the peritonitis having been cured At the autopsy the spleen was found adherent to the uterus and to the pelvic brim

DR GOODELL called attention to the hæmoptysis and hæmatemesis in his case, which were the usual symptoms of a leukæmic spleen, but he had not been informed of them until after the operation had been performed, and therefore he did not have that clue towards forming a diagnosis

(To be concluded)

CHICAGO MEDICAL SOCIETY

Stated Meeting, January 16, 1888 THE PRESIDENT, W T BELFIELD, M D, IN THE CHAIR

(Concluded from page 210)

CASTS OF THE TRACHEA AND BRONCHIAL TUBES were exhibited by Dr F E Waxham, who said The specimen I have to present is a membranous cast of the trachea and of a number of the bronchial tubes I take the liberty of presenting this specimen because it is very rare, indeed, that we succeed in securing a specimen of such extent as this

The history of the case is this The child, a little girl of 4 years, had a very mild attack of laryngeal diphtheria She was convalescing nicely when the occurrence of a croupy cough and sawing respiration indicated very plainly that the larynx was becoming invaded, and within thirty six hours it became necessary to perform intubation in order to prevent impending suffocation For the first twelve hours after the operation the child did very nicely indeed, when a portion of the membrane became detached and the tube was expelled It was necessary to at once reintroduce the tube, and the membrane was pushed down ahead of it, the child was removed and this small cast was expelled the course of an hour it was necessary to reintroduce the tube on account of increasing dyspnæa The child apparently did well for twenty-four hours, after which time there was a peculiar hoarse, freof position the tube, the membrane was not entirely detached, diphtheritic casts

strangling, and coughing violently for a few moments, this large cast was expelled, which is a perfect mem-The diagnosis had branous cast of the trachea and the large bronchial tubes After the expulsion of this cast, it soon became necessary to reintioduce the tube, and the child did well for another twelve hours, when there was detachment of still more membrane, and it became necessary to at once remove the tube tube was removed and still the child was unable to There was simply partial deexpel the membrane tachment of the membrane, it had curled up in the trachea and the child was unable to expel it The child became blue and apparently on the point of suffocation, the tracheal forceps were introduced by the mouth, and a strip of membrane one and onehalf inches in length was removed with the forceps, with immediate relief In the course of an hour or so it was necessary to reintroduce the tube child died about twenty-four hours later from extension into the smaller bronchial tubes

This is another cast of the trachea, not as exten sive as the other, and yet a perfect cast of the When we have this tendency to extensive and deep exudation of false membrane, I believe the case almost invariably terminates fatally, there may be exceptions, occasionally a child after the expulsion of such a large cast may recover, there may be no reformation of the mass, and it is possible that the child may recover, yet these exceptions are few and far between, the termination is almost invariably fatal

In considering these specimens an important question arises Is it possible by any known method of treatment to limit or prevent the tendency through this extensive exudation after tracheotomy or intubation? We are all well aware of the fact, that the greatest danger after tracheotomy and after intubation is the extension of false membrane below the tube into the bronch. I believe that by the use of the rubber coil, by the use of aconite, or veratrum viride or digitalis, it is possible to limit or control this tendency to extensive exudation this case no preventive treatment was instituted, but I shall no longer fold my hands after performing an operation and state that if the membrane extends below the tube the child will die, if it does not the child will get well But I believe it is our duty to use every method possible to prevent or control this tendency to exudation I believe that veratrum or became blue, was unable to breath, and the tube aconite is indicated to keep the pulse below normal In It is particularly indicated in those cases where the system is not exhausted by the diphtheritic disease

DR J A ROBISON As this was pharyngeal diphtheria, I can see very readily how the extension of the membrane down into the trachea occurred quent cough, which was induced with every change is, I believe, a fact that fibrinous casts occur in the This indicated loose membrane below trachea and bronchial tubes more frequently than This fact, however, does not inbut simply loosened, did not occlude the tube en- fluence the treatment which should be adopted, but tirely, but sufficiently to give rise to this peculiar it does influence the method of operating somewhat, cough It was deemed unsafe to leave the child in as, for instance, if we are satisfied that it is a case of this condition, fearing the sudden detachment of the diphtheritic exudation, we should favor the intubamembrane and immediate suffocation, consequently tion operation rather than tracheotomy, because one the tube was removed, and after struggling and of the great troubles in tracheotomy is the extension

of the diphtheritic membrane from the tracheal the membrane will be expelled by the efforts of the wound, whereas, in intubation we would not have child in struggling and coughing, but where it is not this difficulty bation we would be as apt to have the extension of the tracheal forceps and remove it the membrane downwards, as in tracheotomy great danger in intubation is the fact that the membrane is already there, while in tracheotomy there is a wound which is the starting point for infection In this case I think the doctor has suggested a good method of procedure Where intubation has been performed and it is discovered that there is an extension of the membrane into the trachea the proper thing is, on the appearance of dyspnæa or cyanosis, to remove the tube and in case the membrane is not expelled to use the tracheal forceps

It has occurred to me that in addition to the remedies which Dr Waxham has suggested, it might be well to try the effect of mercury It is stated as a therapeutic fact by most authorities on the subject, that mercury has an effect in lessening fibrinous exudation, and it seems to me that it facilitates the elimination of these diphtheritic or fibrinous exudations by giving mercury to the point of salivation remedy which might be used for lessening the heartaction and engorgement of the blood-pressure in the lungs, is calibar bean This is a remedy which the profession uses very little except in tetanus, and yet I have noticed in several cases, especially of ædema due to catarrhal difficulties, that calibar bean given until it lowers the pulse from ten to fifteen beats per minute lessens engorgement of the lungs, and in cases of bronchitis where there is a good deal of swelling of the bronchial tubes, where there are sibilant and mucous râles, I have noticed these disappear very promptly on the administration of calibar bean, and it seems to me that it would be a valuable drug The question arises in my to try in these cases mind, whether, when there is exudation or casts in the trachea or bronchial tubes, the administration of makers emetics is advisable in those cases where there is quite a degree of exhaustion, yet we can facilitate the expulsion of the casts by emetics if the patient is not too much exhausted

I wish to ask if there is not a way Dr Holmes of introducing into the trachea tube, connected with a vacuum and by suction, engaging the membrane so that when the tube is withdrawn the membrane is withdrawn with it

There are several methods of re-DR WAXHAM moving false membrane from the trachea I do not know that there is an instrument corresponding to One is fitted with a rubber the one referred to bulb at one end of a staff which is introduced into the trachea and then expanded, and by withdrawing the staff you remove the false membrane instrument corresponds with the one that is usually employed in removing foreign bodies from the œsophagus In all these instruments it becomes necessary to pass below the obstruction before it can be removed, and there is always the danger of crowding the membrane down ahead of the instrument instead of passing by it I cannot see that these instruments are superior to the tracheal forceps In the majority of cases when the tube is removed,

And it does not seem to me in intu- I find that I can usually grasp the membrane with

NEW INSTRUMENTS.

A NEW BRACE FOR BOW-LEGS BY CHARLES F STILLMAN, M D

CLINICAL PROFESSOR OF ORTHOPŒDIC SURCERY IN THE WOMAN'S MEDICAL COLLEGE OF THE N Y INFIRMARY ORTHOPEDIC SURGEON TO THE N Y INFANT ASSLUM

Bow-legs is a deformity so frequently met with in practice, that an extended description of the condition is not necessary to enable the practitioner to understand the action of the brace here introduced, and which has been devised by the writer

> This brace differs very materially from the heavy double frame usually supplied by the instrument-makers (see Fig A), which supports the limb without exercising much curative force upon the deformity itself

As will be seen by reference to Fig 1, it is constructed upon a new principle, viz, that of combining constant spring-pressure with the support, so that a constant force will be brought to bear upon the bowed limbs at their greatest con vexities, this force being regulated by ratchets placed at the junction of the springs and the main frame of the brace (see Fig 1)

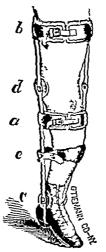

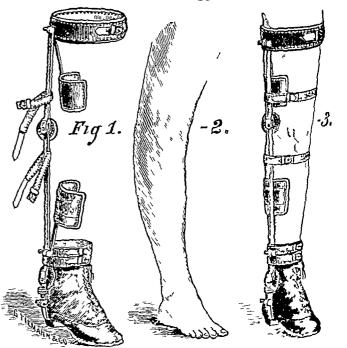

Fig A —I he bow leg brace usually sup plied by instrument

Stillman's Bow leg Brace

foot may be regulated in its relation to the leg, since inversion or eversion of the foot very often accompanies the condition of bow-legs

Cerebral Paralysis in Infancy—General Muscular Contracture in an Infant-Infantile Paralysis from Polio-encephalitis-Moral Obliquity in Childhood-A Book Agent with Small pox

There has recently been organized in the Academy of Medicine a Section on Pædiatrics, and its first scientific meeting was held January 25, with Dr J Lewis Smith, the Chairman, presiding On this occasion the session was devoted to the subject of Cerebral Paralysis in Infancy, and an able paper, that he called a contribution to its study, was read In it he referred to three classes by Dr H Seibert of cases in which the clinical manifestations were all due to atrophy of the brain, although in the first the trouble had its origin in an insufficient blood-supply, in the second in acute meningitis, and in the third in chronic meningitis

In treating of the first variety he gave a detailed description of a case in which there was almost complete absence of muscular power existing from birth Although born at full term, and without syphilitic or other taint, the infant was always puny and poorly nourished When born the cord was found to be wound around the neck twice, and it was to the constriction thus made in utero that the cerebral atrophy At 14 months of age the child died was attributed from capillary bronchitis, and when the brain was examined after death it was found that the layer of white matter was very thin, and the diagnosis of cerebral atrophy was abundantly confirmed by the mi-In the course of his experience Dr Seibert said he had met with four cases altogether in which there was congenital atrophy of the brain, but this was the only one in which he had been able to secure a full clinical history and verify the diagnosis by autopsy

The second variety, he stated, was more common than the first, and of this he related two cases, in one of which a post-mortem examination was made this second class of cases the symptoms were similar in character to those met with in the first, but here the atrophy was due to meningitis resulting in exudation, arachnoid thickening, and sometimes moderate hydrocephalus

The third class of cases, he said, was characterized by increased crying and moaning, with muscular contractions, and sometimes permanent episthotonos, though there were no general convulsions

lustration), and the brace is also provided with ratch- ily increasing, and causing abundant exudation on ets below the ankle joint, so that the position of the the cortex, but running its course without febrile movement He narrated two cases of this kind, occurring in a brother and sister, and in one of them the diagnosis was confirmed by autopsy After lasting for several months the affection terminated in heart-failure, the temperature in one case falling to 96° F, and in the other to 94° In the case in which the post-mortem was made there were no tubercles or tubercle bacıllı found

At the meeting two cases of great interest were presented by members of the Section The first one, by Dr A Caille, was one of General Muscular Contracture in an Infant of Six Weeks The parents were both healthy, and this was the third child of the The other two children were strong and mother well-developed in every way This infant was born at full term, and the head was comparatively large, with a decided flattening on one side of the cranium, but the rest of the body was small and shrunken in The jaw, which was turned slightly to appearance one side, could be opened to only a very limited extent (so that the child was unable to suckle), and there was general contracture of the muscles of both the upper and lower extremities

Dr A Jacobi, after an examination of the child, which was exhibited to the Section, said that the condition present appeared to him to be the result of a meningo-encephalitis which had occurred during The contracture of the jaw somewhat refœtal life sembled that seen in incipient trismus, although the spasm was not so marked as in that affection appearance of the cranium was very much like that met with in cranio-tabes in children a year or more He thought it was doubtful whether galvanoelectric treatment would be of much service in such a case, and that an unfavorable prognosis must be pronounced, although a certain proportion of children presenting the condition vested in this infant (which was undoubtedly very rare), recovered

The Chairman exhibited a case of Infantile Paralysis which he believed to be due to polio-encepha-The child was two years old, and had always been perfectly healthy, with the exception of an attack of diarrhœa, up to May last, when, at the age of sixteen months, while apparently quite well, it was seized with violent convulsions, which lasted from 6 PM to 3 AM, and were accompanied with considerable febrile movement After the stupor commonly following severe eclampsia had passed off it was found that the child had complete paralysis of the muscles on the left side of the body, including the facial muscles on that side The recovery from the facial paralysis was complete, and took place rapidly, while there had been a gradual improvement as regards the muscles of the upper and lower ex-At the present time the child was able to walk, though partly dragging the left leg, and there was still a spastic condition of the toes on the affected side

Dr Smith said that it was his opinion that some of the cases resembling this which had been reported as due to cerebral inflammation, were in reality in-The condition was due to chronic meningitis, stead- stances of cerebro-spinal meningitis Ever since

MISCELLANEOUS.

THE MISSISSIPPI VALLEY MEDICAL MONTHLY, published at Memphis, Tenn , has changed its name to the Memphis Medi cal Monthly, but continues, as heretofore, under the able edito rial management of Drs Sim and Neely The change of name is a decided improvement

THE GERMAN CONGRESS AT WIESBADEN -The seventh an nual German Medical Congress will meet on April 9 to 12 at Wiesbaden, under the Presidency of Professor Leube, of Wurzburg The following subjects for discussion are an nounced "Chronic Diseases of the Heart Muscle, and their Treatment," by Oertel, of Munich, and Lichtheim, of Berne, "Alcohol as a Remedy," by Binz, of Bonn, and von Jaksch, of Gratz, "Prevention and Treatment of Asiatic Cholera," by of Gratz, "Prevention and Treatment of Asiatic Cholera," by Cantani, of Naples, and A Pfeisser, of Wiesbaden Papers are promised on "Floating Heart" (Wanderherz) by Rumps, of Bonn, "Experimental Researches on the Mechanism of Respiration," by Universicht, of Jena, "Combined Degeneration of the Spinal Cord," by Adamkiewicz, of Cracow, "Experimental Contributions to the Dietetics of Digestive Disorders," by Jaworski, of Cracow, "Treatment of Basedow's Disease, and on the Diagnosis of Renal Tumors," by Stiller, of Buda Pesth, "The Excretion and Solution of Uric Acid," by E Pseisser, of Wiesbaden, "The Pathogenesis of the Epileptic Fit," by Binswanger, of Jena, and "On Cryptogenetic Septico Pyremia," by Jurgensen, of Tübingen

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM FEBRUARY 11, 1888, TO FEBRUARY 17, 1888

Capt Wm H Arthur, Asst Surgeon, leave of absence extended two months SO 35, AGO, February 13, 1888 First Lieut Nathan S Jarvis, Asst Surgeon, ordered from Ft Lewis, Col, to Ft Leavenworth, Kan SO 30, AGO, February 7, 1888

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING FEBRUARY 18, 1888

Asst Surgeon F W Olcott, detached from the "Minnesota," and to the "Atlanta"

Surgeon T C Heyl, ordered to the receiving ship "St Louis"

Surgeon H M Martin, detached from the "St Louis" and to the "Swatara"

Asst Surgeon Chus. F Webster, ordered to the receiving ship "Vermont"

Asst Surgeon James G Field, detached from the "Vermont" and to the "Swatara"

A Surgeon Robert Whiting, detached from the "Iroquois"

and to the Coast Survey
Asst Surgeon Elmer C Tracy, resigned, to take effect imme diately

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOS PITAL SERVICE FOR THE TWO WEEKS ENDING FEB RUARY 18, 1888

A Surgeon Eugene Wasdin, relieved from duty at Marine Hospital, Chicago, ordered to Marine Hospital, Mobile, Ala February 16, 1888
sst Surgeon Seaton Norman, relieved from duty at Marine

Hospital, New York, to assume charge of the Service at Evansville, Ind February 6, 1888

ADDRESS

THE PROGRESSIVE AND CONSERVATIVE SPIRIT IN MEDICAL SCIENCE

The Annual Address Delivered before the Boston Gynacologi cal Society, December, 1887,

> BY HORACE C WHITE, M D, OF SOMERVILLE, MASS

In the broad domain of medical science there is room for many laborers, each may cultivate his chosen field for his own profit and for the general The historian records the discoveries and inventions of the past, relates the rise and overthrow of theories, and teaches us of the errors, as well as the truths, which have been promulgated collates from reports and statistics furnishes some imes important, and sometimes unreliable, data upon which to form opinions and theories

The investigator, whether his researches are in 'he laboratory or by the sick bed, is often discoverng new facts and frequently advancing new theories These theories are put to the test and approved or ondemned, by him who stands in the presence of build anew lisease and death, and who, furnished and equipped y the results of the labor of his predecessors, and is own experience, takes the responsibility to act Inowledge is vast and life is short Each in his wn sphere may act his part

/ The advanced thought of to day is the conservasm of to-morrow The winnowing sieve of expeence separates the grains of truth from the chaff of rror, the former is eternal, the latter is the rubbish f the past The world is full of books, but a not The late Prof Cleaveland, of Bowdoin Colge, gave as the best definition of science, "Classifi ation and induction" One of his successors denes Natural Science as "that theory which will cplain most of the phenomena,

.The first definition is correct for exact science ily, otherwise we may classify well proven facts, id those, often warped and twisted to prove theo s which we have been taught, with what time gressive and conservative oves to be but error We must take the second finition to apply to Medical Science, if indeed it t can be called a science

Theories must frequently be changed with increas-3 knowledge New facts, both physiological and ent, and often a radical change in theory

The microscope is revealing hitherto hidden mys-Collateral sciences are developing unknown forces, and opening up new fields of investigation, while more scientific observation and careful recording of cases gives us much data upon which to revise long unchallenged opinions But not until we can comprehend that seeming impassable barrier, a want of knowledge of the vital force, or can get some conception of the origin and nature of force as applied in the natural sciences, can we expect to attain anything like permanence in our theories Carlisle says "Science has done much for us, but it is a poor science that would hide from us the great, deep, sacred infinitude of Nescience, whither we can never penetrate, on which all science swims as a mere superficial film " "The world," he says, and he might with equal truth have said the human body, "after all our science and sciences, is still a miracle, wonderful, inscrutable, magical and more, to whosoever will think of it " And yet each generation goes building up new theories and fortifying them with facts, both seeming and real, until its successors, or the advanced thinkers of the day, tear them down to

Against all these innovations stands conservatism, defending the theories of the past as a patriot defends home and country, and not only standing on the defensive, he sometimes attacks what he believes to be his enemy, with all the power at his command, using even sometimes the sharp sword of ridicule and sarcasm

Have not these theories stood the crucial test of experience? True, they sometimes failed, but was not the failure merely an exception so conveniently ery large volume would contain all well proven believed necessary to prove the rule, or explained as an accident, which might have been avoided?

These well-tried theories he is loath to give up even when, in the light of new truths, another will explain more of the phenomena

> "My very chains and I grew friends, So much a long communion tends To make us what we are "

The earnest seeker after truth should be both pro-

This is an age of brilliant scientific investigation and dazzling theories, and while we should not be captivated by their mere brilliancy, we should give them an unprejudiced examination and an impartial judgment Koch, Pasteur, and others, by their in-, thological, require an almost continual readjust- vestigations and speculations in biological germs, have given a new impetus to scientific thought in its relation to pathological processes New theories have been founded and old theories threatened New theories Honest conservatism will not be hasty to accept the mable value to surgical science which the discovery new, but it will be ready to listen, to examine, and of the anæsthetic virtues of sulphuric ether has been to acknowledge that which time and experience | Shall we not, then, take warning by the past, and,

grown out of the germ theory so ably taught by Lister and his zealous disciples, has proved that scrupulous cleanliness is an essential factor to success in all surgical operations, and that when experience has eliminated some of the hasty conclusions, much of value will be left, and that many of the phenomena of pathological processes are best explained on these theories Scientific thought is ever pro-New theories are evolved from the old The originals," says Emerson, "are not original"

There should be nothing but generous contention between the progressive and conservative scientist All new discoveries or innovations upon the customs or thought of the times are liable to encounter an ungrateful and often persecuting spirit The torture of Galileo, the imprisonment of Columbus, the ridicule and misrepresentation with which the new discoveries of Harvey and Jenner were received by even the scientific men of their day, are only illustrations of the fact, nor can these examples be credited wholly to the ignorance or bigotry of the past, the same spirit often shows itself in some form at free discussions cannot but be of great value to the present day

Some of you gentlemen can remember the abuse heaped upon some of the most eminent surgeons of Boston when they first tested the anæsthetic virtue of sulphuric ether, and this severe criticism, too, by influence upon society work, and in the impulse some of the leading medical journals of this country For the benefit of younger members, I quote one of scine in this country

the many criticisms of that day

The Philadelphia Medical Examiner, after detailing the reports of its trial by Drs Warren Haywood and "We are persuaded that the surgeons Bigelow, says of Philadelphia will not be seduced from the high professional path of duty into the quagmire of quackery by this will-o'-the-wisp, and, if any of our respectable dentists should be tempted to try this new patent medicine, we advise them to consider how great must be the influence of an agent over the nervous system, to render a person unconscious of pain—the danger there must necessarily be from such overpowering medication, and that if a fatal result should happen to one of their patients, what would be the effect upon their conscience, their repu- study which will be felt, may we not hope, for many tation, and business, and how the practice would be likely to be viewed by a Philadelphia court and ably sustained, and the enthusiastic attendance upon jury? We cannot close these remarks without again its meetings proved the interest which was felt in expressing our deep mortification and regret that the this department of medical science eminent men who have so long adorned the profession in Boston, should have consented for a moment to set so bad an example to their younger brothers as we conceive them to have done in this instance If such things are to be sanctioned by the profession, ling, did so much to deserve success He was ably there is little need of reform conventions, or any assisted by several other member our Society, other efforts to elevate the professional character, by many physicians and quacks will soon constitute one fra- from ab ternity "

How oddly this sounds when we remember the priceless boon to suffering humanity and the inestiwhile we may be conservatively slow in accepting All must acknowledge that the practice which has new theories or in attempting dangerous experiments, we should be equally careful not to hastily condemn every innovation upon the accepted theories and practices of the past, honestly seeking after truth and fearlessly defending it The rapid growth of medical societies and their divisions into the various specialties, during the past few years, gives opportunity for full and frequent discussion on topics of interest to the profession New and old theories must stand on their merits Their disciples and defenders must at all times be ready to give a reason for their faith and defend it from assault, here each has a chance to question and demand proof, and each has an opportunity to prove, illustrate, and relate his experience If it possess merit it will with stand all the arguments which can be brought against it, or all the ridicule which may be heaped upon it, and come out like wheat from the winnowing mill or new coins from the mint, but if it is wanting in merit it will soon take its own place among the heaps of useless rubbish with its kindred companions of exploded dogmas and worthless inventions Such true scientific knowledge if carried on with no feeling but that of generous contention and for disinterested purposes

The past year has been a memorable one in its which has been given to the scientific study of med-

The meeting of the Ninth International Congress, at Washington, bringing together as it did eminent scientific men from different parts of the civilized world, each contributing by his presence, and many by their labors, to enrich the feast of medical scientific thought and fraternal relations The amount of valuable original work was not small, and if, as Lowell says, "Originality consists quite as much in the power of using to purpose what it finds ready at hand, as in that of producing what is absolutely new," then the amount of original work was indeed Not alone in the work vast as well as valuable there produced will the influence of the Congress be felt, but by the stimulation to investigation and The Section of Gynecology was years to come Much credit was due, and cordially awarded to, the President, Dr Marcy, an honored member of our Society, whose indefatigable labor and eminent ability in organizing the Section, and whose courteous manner in presidountry and ent ge ota terested

rank in the profession in the countries which they represented gave great interest to their papers and discussions, were Drs Martin, of Berlin, Grailly Hewitt, of London, Reed, of Glasgow, Apostoli, of Paris, and Cordes, of Geneva, with many others of first rank in this and other countries With this array of talent so well organized, the meetings were interesting and profitable Among the subjects discussed which have been considered by our Society with interest during the past year, was that of uterine myoma. Its treatment, in suitable cases, by ergot, was ably presented, as also by electricity, which called forth much discussion of using electricity in gynecology was fully explained Dr Martin's operation for vaginal and discussed several of you gentlemen had the pleasure of witnessing while he was in Boston, was elaborately exme to give even a synopsis of what was presented of reproduction interest to our Society

ought to do efficient service in its important and honspirit both progressive and conservative its membership ardent and enthusiastic investiga- functions tors, men who do not feel obliged to stop where their nancy, so familiar to you all predecessors did, or to take as proved all they have been taught, but who, with clear heads and steady by the light of advanced scientific thought and with all the appliances of modern art It has also men with the experience of years upon them, men who have had grand success with old theories, and who have a right, by reason of their past success, to be conservative and hold fixed opinions Some who have spent much time in the hospitals and laboratotories studying their specialties with the best advantages and under the great masters of our art, and respects, have been taught independence and selfwere obliged to act with the best light they had and watch the results with no one to counsel them or share the great responsibilities, and some who have just entered upon the responsible duties for which they have been for years preparing themselves, full of enthusiasm and hope Our Society is also honored by having in its membership, ladies, possessing not only the education and experience of the sterner sex, but also a keener sense of the wants and of the peculiar nature of the disease of which our specialty calls upon us to treat

In our list of corresponding members may be found the names of gentlemen who are known the world over, and who are acknowledged as leaders in gynecological studies and practice. With this array of talent working harmoniously together, the possibilities of our Society for good to each member and the communities in which we live, are very great.

UTERINE MOLES

Read before the German Medical Society of Philadelphia, Feb ruary 13, 1888

BY EDWIN ROSENTHAL, MD,

ASSISTANT DEMONSTRATOR OF CHEMISTRY JEFFERSON MEDICAL COL LEGE FORMERLY PHYSICIAN ACCOUCHEUR TO THE WOMAN'S LYING IN HOSPITAL OF PHILADELPHIA, ETC

The most important of the internal organs of generation is the uterus Its structure, anatomical Dr Apostoli's method | character, physiological attributes and pathological changes have received the most attention from the zealous investigation not only of the obstetrician total extirpation of the uterus for carcinoma, which and gynecologist, but of the physiologist, and last, but not least, the pathologist The peculiar and especial office that places it in the foremost rank of plained and illustrated, but space will not permit the anatomical structures in the woman is that of After copulation, should fecundation take place, it then becomes the nest upon which the The Gynæcological Society of Boston can and fecundated ovum rests, grows, matures, during that period which we term gestation, and at the expiration orable field of labor Its talents are versatile, its of this nearly uniform period it expels its contents It has in labor, and then resumes again its normal size and These changes comprise a normal preg-

But this evening I will speak of the pathology of pregnancy, that is, of one of the functional derangenerves, are carefully exploring in untrodden paths ments that occur in the pregnant woman, in which there may be an accidental lesson of the ovum, spontaneous to the ovum, which always ends in death, and which we will designate as Molar Pregnancies

I must, however, preface my remarks with this observation that whilst there are certain forms of moles termed the false or spurious moles, which have nothing at all to do with conception and which, for the proper understanding of our subject, must be spoken of and described, I may be open to your criticism some who, although less favored, perhaps, in these by speaking of these affections under the term pregnancy, but as I before observed that the uterus exreliance from necessity while treating all "the ills pels its contents by what we term labor, and as labor which flesh is heir to" in country practice where they is the ultimate result of pregnancy, the expulsion of a spurious mole has the same physiological action as that of the true mole, probably and properly termed a spurious pregnancy, at any rate, the women suffer pain quite equal, and a virgin will remain a virgin, a mole notwithstanding

Historical Sketch - Moles were known to the ear-This can be attested by the fact that liest writers Hippocrates, Aristoteles and Galenus had been acquainted with them, speaking of them and understanding them to be degenerated ova, which we to-day know as vesicular or fleshy moles The Arabians gave a greater field to their designation of They understood a mole to be not only the uterine contents, but also any tumor which might lay in the cavity or in its walls. Then again, at a later period, a difference was shown in moles, and then was spoken of true and false moles, the product of conception and not of conception

Schenk v Grafenberg, in 1565, was the first to describe the vesicular or hydatidiform mole (Blasenmole) The nature of this product was for the great-

est period obscure From the end of the last century exercised in differentiating these false moles from even until a recent period this was looked upon as true ones. Difficulty may arise when the discharged true vesicular worms Whilst already Ruysch (who tissue is the membranes of membranous dysmenorwas still uncertain whether they were a pathological rhoa, where this tissue may be mistaken for true deproduct of pregnancy), looked upon these cysts as cidual membranes The circumstances attending an alteration of the villi Velpeau and Johan Muller each case should receive the earnest scrutiny of the disputed that the vesicles were true cysts problem from whence originated this growth? was evidence should be gathered were there any previunsatisfactorily answered by different theories Gierse ous attacks? note the absence of the signs or sympand Meckel seek the origin of the product to be a toms of pregnancy, and so on hypertrophy of the villi (zotten), whilst H Muller charged mass, should this happen to be complete, the exochorion, and Mettenheimer the cellular tissue Virchow finally cleared away the obscurity and that of the cervis, which is never observed in true brought light on this subject He proved that vesicular or hydatidiform moles (described also by Hil-the presence or absence of the fecundated ovum debrandt as "fibrous my vomata" of the placenta) were | Blood clots, polypi, and small fibroids or portions of a hyperplasia of the mucous membrane—the elementary bases of the finer tufts of the chorion (Cho- naked eye or microscopic examination Schroeder quotes cases of "diffuse rionzotten) my oma" of the placenta, by Breslau and Eberth, of impregnation and Spaeth and Wedl

moles into two great classes a, the false, b, the true moles

True moles are subdivided, as regards their physical character, into fleshy and vesicular or hydatidi-The fleshy are again divided into fatty, carneous (steinmole), etc Moles have been designated by different names moon calf (Mondkalb), devil's brood (Teufelsbrut), wind-egg (Windei), sun child (Sonnenkind), Neirenkind, Kielpopf, Missge-By the professional they are designated by their contents blood mole (Blutmolen), water mole (Wassermolen), air moles (Lustmolen), hair mole (Haarmolen), cartilaginous mole (Flechsenmolen), bone mole (Knochenmolen), and calcareous mole (Kalkmolen)

A Spur sous Moles —I shall speak rather briefly of this portion of my paper As an independent affection, existing uncomplicated, I believe it to be impossible Its mention here is to open the way for the discussion of the more important variety

Mauriceau believes that moles could not exist without impregnation, that it was always the offspring of intercourse In his 105th aphorism (Traité regular medical attendant She was suffering from des Maladies des Femmes Grosses) he says femmes n'engendrent jamais des moles, si elles n'ont uterine contractions. The flooding was very prousé du coit " This Alexander Milne, of Edinburgh, suse cannot subscribe to, believing that cases occur, nay, more, having met with them, where fleshy masses have been expelled from the uters of women who If virgins expel certainly never had connection such things, then, they are not to be impeached, to do so would be unjust

Various substances, organized or unorganized, may be discharged from the uterus of the virgin, such substances as clots of blood, membranous shreds, or even whole membranes, as well as fibrinous materials These may even have the shape of the uterine cav- History of general good health, no syphilitic or ity, and may come away naturally or must be removed, and which have nothing whatever to do with Dr Julius Kaemmerer, who treated her for several fecundation, and are termed spurious moles

medico-legal view, and the utmost care should be the same case with precisely the same symptoms

The attending physician All circumstantial and direct Examine the dis we may find the opening of the Fallopian tubes and The microscope, however, will determine decidua large ones should not be difficult of recognition by

B True Moles — True moles are always the result The villi of the chorion may become distended with fluid collecting within them, Moles and their Synonyms - Obstetricians divide | causing them to swell and assume the form of rounded vesicles comparable to gooseberries or grapes, resembling hydatid vesicles, and on account of this analogy they were for a long time supposed to be true hydat-Or an extravasation of blood may take place between the maternal and fœtal structure of the fecundated ovum or into the tissue of the latter, producing a fleshy mole The embryo may become mummified, or may speedily disappear in the early stages, and then we meet only with the membranes or appendages

Two chief varieties of true moles are at present recognized, namely 1, the fleshy, and 2, the vesic-

ular or hydatidiform mole

I Fleshy Moles — These I believe to be the most frequent My colleagues who are acquainted with this formation and myself have met with these cases more frequently than the hydatidiform I shall present the histories of a number of cases which I have met in practice and in that of my colleague, Dr L Wolff, which may describe the conditions met with

Case 1 —Dr Wolff's case History incomplete The doctor was called to a woman in absence of her "Les uterine hæmorrhage Besides this, she had painful On examination a roundish mass was discov-Tamponnage and ered engaged in the os tensi internal administration of ergot failed to remove this, although it gave rise to violent contractions Expulsive efforts were much marked, but with no Dr A, for whom Dr Wolff was attending, result returned in a few days, and afterwards informed him that the case was one of a fleshy mole, firmly adherent to the uterine fundus, which he had to detach with a blunt hook and curette

A German woman Case 2 — Dr Wolff's case Previously treated by my preceptor, other taint They were spontaneously deof the kind before Their significance is of some importance from a tached after much hæmorrhage. Dr Wolff treated

previous suppression of the menstruation of two or three months, beginning hemorrhage and pain, becoming worse as the case continued, the mass com-

ing away naturally

Case 3 - Dr Wolff's case A German woman, strong and healthy appearance, et 30 years been complaining of uterine pains, bearing-down pains, for some time, with slight hemorrhage which became very profuse, for which Dr Wolff was sent The uterine contractions were much greater than he had previously met with Digital examination revealed a round, soft body engaged in the os tensi, it was firmly adherent and could not be re-Tampon and ergot had moved between the fingers no effect, though frequently repeated As the hæm orrhage continued so profusely as to endanger life, removal was proposed and consented to This was accomplished by means of the Beecher placenta forceps after considerable difficulty, the adhesions being so firm, and effected only after twisting or ro-The adherent or pedicular portions tating the mass were found quite distinct, and had undergone partially but distinct fatty degeneration

Case 4 -Dr Wolff's case Mrs C, an Italian woman with a history of a number of miscarriages Was attended by Dr H, who called Dr Wolff in consultation The doctor found the patient almost pulseless Dr H was not there when the doctor He had, however, succeeded in controlling arrived the hæmorrhage by means of the tampon and ergot Stimulants were administered and twenty-four hours subsequently the tampon was removed by Dr H, who insisted that the case was one of miscarriage only, and predicted that the placental residue would be found in the vagina after removal As no fœtus had been expelled, and no history of fecundation, Dr Wolff claimed the probability of its being a mole Tampons failed to dislodge it, both in the first attempt or any repetition, therefore removal was con sented to, and with the Beecher forceps a fleshy mole was removed, part of which had been previously broken up and removed by Dr H After removing all particles with the blunt hook and curette and irrigation with hot water, the hæmorrhage ceased, the uterus contracted, and a slow convalescence ensued from the extreme an emic condition

Case 5 -Mrs N, æt 35, had never borne children Was called to see her for intense uterine pains with slight hæmorrhage She had suppression of the menses of ten weeks' duration Morphia was administered hypodermatically On the third day hæmorrhage became more profuse, tamponnage and ergot were resorted to, which caused the expulsion of a flesh mole the size of an orange, round and somewhat coagulated blood When incised, the texture was somewhat compact, and in the centre was found a small cavity, fined by a serous membrane and coneither the fœtus or cord remaining rapid recovery

Case 6 — I was called by a midwife to see a Hun

40 years of age, well nourished and fleshy been in labor about twenty-four hours, and the midwife was at a loss what was presenting, which was shared by myself There was a slight hæmorrhage. with uterine contractions. The uterus was open about the size of a dollar, soft and pliable, and a tendency to dilate In several hours a large fleshy mass was discharged, about the size of a foetal head. which presented the same physical characteristics as the previous case, except in the walls of the mole, which were probably 3 inches in thickness, small cavities were found filled with blood In its centre the same cavity as in the previous case was found (which, in regard to proportion to the entire mass, might be placed as 1 to 20), lined with serous membrane and containing some fluid and nothing more

Case 7 -A Polish woman, Mrs H, æt 38, mother of five children, the youngest 3 years Had had three miscarriages, but none since the last birth Had suppression of the menses for over a year and supposed herself to be passing the menopause four months has had constant dribbling of blood from the uterus with intermittent pain I was called to see her, and on examination could easily pass my finger into the uterus Presenting at the os, and movable, I found a mass of tissue This I attempted to remove with curette and blunt hook, but without By means of this placental forceps I was success enabled to remove the mass, previously crushing it so as to remove it It was a mole, probably one of those termed the carneous, of very dense fibrous tissue, with here and there small pellicles of calcareous The woman made an excellent recovery deposits

Case 8—B F, an English woman, æt 33 years, well nourished, family history good Has had four miscarriages, and then one pair twins, one year after gave premature birth to twins, both dead, probably seven month fœtuses A year after this I was in attendance and she was safely delivered of a full term child, and with the afterbirth, seeming to be adherent, was discharged a large fleshy mass, having all the characteristics of a fleshy mole Its size was that of an adult head, it was pliable, easily moulded, and was brought away without any difficulty it at first for a monstrosity, but it had no resemblance in any of its features I incised it and found a small cavity containing a small amount of fluid This case was unique, and I might have doubted that the mass as a fleshy mole could exist with the living fœtus, but since then I have read in an excellent monograph by Alfred Wiltshire, Physician Accoucheur to St Mary's Hospital, London that such a state of things was said to have occurred on the occasion of the birth of the celebrated anatomist Beclard That, in fact, twin firm, presenting an irregular surface covered with pregnancies may occur where degeneration affects the membrane of but one ovum

ETIOLOGY —As before mentioned, extravasation of the blood between the maternal and fœtal structures taining a small quantity of fluid Not a vestige of of the fecundated ovum, or into the tissues of the She made a latter, appears to be the active agent in the production of the fleshy mole, though it is difficult to determine the agencies whereby this condition is brought garian woman who was supposed to be laboring under about Diseased state of the decidua may doubtless a beginning miscarriage She appeared to be about result when pregnancy supervenes upon chronic en-

In a case I treated wherein pregnancy dometritis supervened, a miscarriage resulted. I did not examme then, which probably I would do now, the pro- the same may be said of acute specific diseases where ducts of this miscarriage of blood into the maternal structures may occur from cardiac disease, though my experience teaches me that women suffering from cardiac diseases very rarely become pregnant

Frequency — From the number of cases presented this evening it may appear that moles of the fleshy variety are not infrequent. I am led to think that they are more frequent than one supposes The lack of knowledge, coupled with the ridiculous faith placed in the assertions of the women who have them, leads Again, their appearance, likthe attendant astray ened to that of placental tissue, especially when blood is effused into it, besides where the mummified fœtus | serotina is still in existence, or the remains of the fœtus, of the cord, etc, leads the physician to a diagnosis of a simple miscarriage and not that of a molar pregnancy Fleshy moles are by far more frequent than the ad infinitum, at the point corresponding to the serovesicular or hydatidiform variety, and are not an uncommon concomitant to frequent pregnancies or miscarriages

Symptoms —The immediate symptoms are those of a threatening miscarriage The premonitory symptoms are likened to those of the very earliest months Absence of the placental souffle and of pregnancy the positive signs of pregnancy, with suppression of the menses, are among the signs I and my colleague were only called at the threatening abortion not believe that any positive symptoms exist by his description of a fleshy mole as follows

its expulsion

Course -The course of the molar pregnancy of Generally at three the fleshy variety is variable months nature seeks to throw off the mass . Hæmorrhage comes on about this period, and then it is the little product escape, leaving the membranes simply a question of time when the uterus expels its behind. These envelopes may undergo various modicontents

DIAGNOSIS -The diagnosis of the fleshy mole I Suspicion may arise when should deem impossible the patient has had one before, but as regards posi-It can only be tiveness, I think it out of question made when you have the tumor in your hand

Prognosis -All the cases here quoted ended Prompt treatment should be the rule favorably Should danger arise from the excessive hæmorrhage, the tampon is always a safe and efficient remedy Some cases of extra-uterine moles which authorities quote, that have been met with in the ovary and abdomen, and the cyst given way, causing death, are Sometimes these cysts have of course unfavorable opened into the bladder or bowels, the result being the same Still, the same chances which extra-uterine pregnancies have in antiseptic surgery extra-uterine moles may have, and the prognosis modified ruary, 1840) relates one case Peritonius may result tremely marked, and in rare cases calcareous degenfrom the misuse of instruments, causing death Hæmorrhage might, and pyæmia and septicæmia, ecc , may cause death

PATHOLOGY —The pathology of fleshy moles is still shrouded in obscurity Heart disease, causing an it is looked upon as a true mole

effusion of blood, again, syphilis and other blood dyscrasiæ, appear to exert an influence, and perhaps It is said that an effusion they fail to excite abortion. Whatever may be the exciting cause, when once blood has been effused into or between the fætal and maternal structures, the vitality of the embryo is speedily compromised The common result is abortion, but, should not the whole be thrown off, growth may take place in the remaining tissue, while the effused blood becomes organized and gives bulk to the mole. In a case of cancer of the ovary, posted by a friend, I removed some time previous what I termed a retained placenta, which was in the uterus of that unfortunate woman five months

The maternal placenta is formed by the decidua The fœtal placenta is formed by the villi of the chorion, which, having originally covered the entire surface of the ovum, atrophy over the major part of the surface, while they ramify and develop, tina, where they become imbedded and constitute the vascular mass known as the placenta. To study changes in the chorion amounts to studying the lesions of the placenta, and the reverse Now, these changes may relate to each of the placental elements, t c, the vessels and the villi

Not infrequently a considerable effusion of blood takes place immediately beneath the amnion, encroaching greatly upon and sometimes rupturing the amniotic sac, and Cazeau (1876, page 578) gives which accurate diagnosis can be made previous to further happen that the placenta, maintaining its vascular adhesion with the internal surface of the organ, continues to develop after the child's death, the cord and fœtus becoming atrophied, and then completely destroyed, or, indeed, the ovum may rupture, and fications, but the most common is the morbid product known as a fleshy mole." The inner aspect of the cavity then presents an irregular nodular appearance, and is of deep red, almost black color the nodules are incised they are seen to be composed The foeral surface contains nuof firm blood clot merous blood cysts The tissue microscopically I present here

If not immediately thrown off, growth may continue in the tissues, and a bulky fleshy mole results The connection between the ovum and the womb being most intimate at the placental site, changes go on most actively at that spot, and when blood is largely effused here it constitutes what is called apo-Examination of the carneous plexy of the ovum moles shows the decidua vera to be the chief seat of degenerative changes, but in all cases chorion villi may be found, though much altered by fatty and molecular matter Fatty degeneration may be exeration may be met with, forming what the Germans term the Steinmole, but such degeneration of other uterine bodies may occur, as fibroids, etc , and therefore clear evidence of conception should exist before Blood polypi are

delivery at full term, in which, organization having for treatment and our recognition was mutual taken place and communication being established between the clot and the uterus, degenerative changes | her to the Women's department go on to the extent of calcification, whereby the socalled Steinmole may be produced

2 Vesicular Mole - The vesicular, hydatid or hydatidiform mole is the better understood, if not the more important variety of the true mole, and has received the most attention of the pathologist have seen it but three times, twice in one person

will relate the cases here

Case I — Mrs S, an American lady, æt 28 years, brunette, a little above the middle size, well nourished, had one child, æt 5 years, and two miscarriages, one of which was twins, I attended her in both I was engaged to attend her for what we both thought a normal pregnancy She could not tell me how long she had been pregnant, but from indication I judged Her family history is her to be about six months I have some doubts as regards her husband's morals though I have never treated him She sent for me on account of a show I made no examina tion, but treated accordingly She increased rapidly in size, at the same time the dribbling of blood continued, and she says, she felt not at all like carrying her first child, and therefore feared that all was not She was confined to her bed and probably a month later I was again sent for, she having at my former visit requested me to wait until I was sent for I saw her very anæmic, having constantly lost blood and small masses, which she told me were blood clots Examining the abdomen by inspection and palpation revealed a boggy sensation, the abdomen had the same appearance as in dropsy, the uterus was not at all conical but seemed transversely more wide

Digital examination revealed a protruding mass through the os, and withdrawal brought away numerous vesicles The diagnosis of vesicular mole being explained, permission was freely granted to remove the mass, which was with some difficulty ac complished The patient making a very slow and tedious convalescence

Case 2 —Mrs L, present age 42 years, at my attendance six years ago 36 years A Russian woman, well nourished, at the present time she has given birth to thirteen living children, the oldest 23 years, the youngest 18 months, eight are still alive has had two living children since my attendance in She was married at the age of 15 1882 Her husband has perfect health as regards specific diseases When I attended her in 1882, I was called for a hæmorrhage from the uterus This was very profuse On examination I found a large mass filling up the whole vagina and protruding externally, which I at first mistook for a blood-clot The tissues of the mass were easily torn in attempting removal, which was accomplished with great difficulty The mass I removed by scooping out the tissues with my fingers, and a uterus and vagina with vinegar and water injections Three or four days after my patient mysteriously dis- nancies, sometimes during pregnancies

occasionally met with, arising after miscarriage or brought her youngest child to the Jefferson Hospital complained of some uterine trouble, and I referred Five days afterwards I was sent for

She was in bed, complained of slight pain and hæmorrhage, and I gleaned the following history Since I removed the previous mole in 1882, she had been in good health, and had given birth to two living children, the youngest was 16 months old Since then her health has been variable, and for the last five months she had constantly a uterine hemorrhage, intermittent in character For this she sought treatment at the hospital, and since then has had pain of variable intensity whilst the slight hæmorrhage ceased, to give place to more copious hæmorrhage for which I was sent for On examination I found the vagina filled with a mass of tissue and bloodclots, part of which I removed at once and have here The next day removal of other portions was undertaken, but with great difficulty, the parts being torn in the attempt Ergot and tamponnage with irrigations and curetting, enabled me in about ten days to remove the whole of the uterine contents

My patient is making a very slow and tedious recovery and is still under treatment for symptoms of sub-involution

ETIOLOGY—Like fleshy moles, the etiology has not been fully explained We are still not assured whether the cause of this variety is primarily in the ovum, or in the diseased deciduæ, or if it originates from the maternal cause—the blood of the mother Ruysch, Scanzoni, and Graily Hewitt, find it in the death of the fœtus, but moles have been found with It is not the death of the ovum living children alone that can be directly the cause even if a neoplasm should ensue after such a death. That the cause may he with the mother we have such cases on record in which the desiduæ is diseased, or other pathological affections of the uterus exist, and where moles are found more than once in the same woman Virchow attributes it to endometritis, and this is the generally received opinion in Germany to-day Mayer, Depaul, Harkin, Puech and Hecker think that in the formation of the allantois is the origin of the anomaly, as we find cystic or vesicular or hydatidiform formation in the placenta or in the villi of the chorion This may be reasonable to suppose the reason that one ovum may degenerate into a mole whilst the other may be perfectly normal Charpentier, (Vol p 253, Ency Obstet and Gynæcol) says "It is probable that the myxomatous lesions begin in the abundant mucoid tissue of the villosities, and that

this tissue becomes infiltrated with fluid Frequency - Vesicular moles are rare, though partial degeneration of placental tissue may make it more frequent It is found oftenest in multipara of 25 to 40 years A molar pregnancy is apparently, to a certain extent, a predisposing cause large quantity was thus removed I irrigated the instances vesicular moles repeat themselves more than once,in the same woman, sometimes after pregappeared, having forgotten to pay me, and I never (Virchow's Archiv 1870, Bd 41, p 461) relates a san her again until three months ago, when she case where a woman eleven times carried a mole

and at the same time a full-term child Depaul-in the same journal—relates a case wherein a woman had a mole three successive times Bloch (Jas Blasenmole, Freiburg, 1869) says age show a greater tendency or disposition to moles First pregnancies are rarely so affected One pregnancy quickly following another point to a predis-

posing cause to molar pregnancies SIMPTOMS —In the beginning are rarely marked The same symptoms as of ordinary pregnancy are The bulk of the uterus those most usually found increases with great and disproportionate rapidity There is a tendency to the loss of ovoid form and the | be attributed directly to the mole is that of rupture assumption of the globular or more transversely wide of the uterus mentioned by Madame Boivin shape Generally there is evidence of some derangement, by the appearance of a watery and sanguineous discharge, later on small vesicles come away, and then the diagnosis is clear, but in their absence diag-According to Percy, there is an nosis is guarded alternation of small hamorrhagic and watery flows, commencing in most women at the second month, and continuing at longer or shorter intervals until Gardien observes that the expulsion of parturition hydatids is usually accompanied by hæmorrhage and syncopes, and Depaul has observed the same peculi-This mole can reach the size of a child's head and weigh 1000 to 1500 gms or more

Physical examination often yields important infor-Palpation may give, as Leishman remarks, a significant sensation of bogginess, with absence of the irregular fœtal hardness Hardening under manipulation is very significant of the uterine nature of the tumor On examination, a doughy sensation may be experienced in the lower segment of the Should the os be open, vesicles may be felt To the touch they somewhat resemble recent bloodclots

Course -From three to four months uterme contractions set in with pain, discharge of blood, serum, mucus, etc, vesicles come away and the mass is slowly discharged It is a very tedious process, as it is a rarity for the mass to be discharged in toto Generally it is discharged in pieces and the woman fect suffers greatly from loss of blood, shock, etc rule, the whole course of this disease is from three to six months (Kleinwachter) though cases are on record where its course was prolonged to nine or ten months, or longer even than normal pregnancy Underhill (Amer Jour of Obstet, 1879, p 182) relates a case of molar pregnancy which lasted one year rare thing for a normal and molar pregnancy to take place at the same time As an exception Caspari relates (in Virchow's Archiv Abgang der Mole in mole en masse der 20 Woche and 3 Tage spater Jener einer 4 monatlichen faultodted Frucht) a casein which a mole was discharged and three days later the fœtus in a state containing a fœtus or parts of one, and possibly fluid of putrefaction

disease is impossible. If the uterus enlarges too the umbilical cord, the fœtus having been dissolved rapidly, that is disproportionate to the time, vesicular moles may be suspected When mucus, blood, and above all, vesicles are discharged, ther the diag- less complete effacement of the central cavity formed nosis is assured The older authors did not consider by the amnion, the place of which is taken by a mass the mole as always due to pregnancy, and claimed of soft, yellowish, spongy tissue

that the mammæ did not develop That is not the case, for Cartercau has demonstrated the abundant They said the mother did not feel presence of milk "Women of advanced life, but there are moles where the child is born liv ing and at term Finally, the uterus shows the ordinary inequalities, and all the signs of pregnancy nausea, vomiting, etc., may be present

Prognosis —For the mother is always grave The source of danger is the frequency and intensity of the hæmorrhage In many cases the mother succumbs, not from development of the mole, but from The only instance where death could hæmorrhage hæmorrhages are usually moderate at first, and usually only become serious towards the end of pregnancy, and at the moment of expulsion If a physician is in attendance the prognosis is more favorable than when such pregnancies are left to themselves In some cases the vesicles are retained so closely to the uterine wall that it is with difficulty they can be dislodged, care should be taken in removing them, again, if the tumor be of extraordinary size, the prognosis should As a rule, we should look with signifi be guarded cance upon the size of the mole, the partial or total extraction, and the intensity of the hæmorrhage, be-In those instances where fore we give an opinion women have had several vesicular moles, the prognosis is more favorable

For the child the prognosis is always serious If the fœtus be not liquefied or dead, it is always injured

and ailing, and ill-prepared for life

PATHOLOGY —It is well to state at the onset that the name "hydatid" mole is erroneous and misleading There are no true hydatids or echinococci in it, the physical arrangement of the vesicles is different True hydatids are closed sacs, contained one within another, while the vesicular mole is formed by sac-It was formerly cules growing from one another supposed that they grew from a common stalk, and they were likened to a bunch of grapes or currants, but for the reason given above the simile was imper-

The vesicles vary in size from a chestnut to a pin's head or less, usually they are about the size of small currants, and as a few may from time to time escape accompanied by more or less sanguineous discharge, Gooch's simile of "white currants floating in red currant juice," is a very apt one

Dubois and Desormeaux describe three varieties of hydatidform moles 1 The embryonal hydatid mole 2 The hollow hydatid mole 3 The hydatid

The first variety consisting of a membrane, vesicular on its outer surface, with an internal cavity

The second kind is like the first, save that its cav-DIAGNOSIS —The diagnosis at the beginning of the ity contains only fluid, and possibly a remnant of

The third variety is distinguished by the enormous development of the hydatid bodies, and the more or carefully investigated by Robin, Barnes, Metten-hyperplasia results heimer, Paget, Henitt and others According to hydatidiform mole has its origin in the chorion, and the microscopical examinations of Prof Robin exhibited still more clearly the true nature of the disease by showing that the envelope of the vesicles have all the anatomical characteristics of the walls They become dropsical, of the villi of the chorion swell up, the pedicle of these dropsical villi is formed of the base of the villus affected Goocn likened them to currants, Cruveilhier to grapes These speouter surface of the little cysts, formed by the transformation of the cells of the villi, a new growth of villi arises, and that these again are morbidly altered into similar cysts, and so on Dr Graily Hewitt (London Obstet Soc Transac, vol 1, p 249) says there is no new formation at all

All authorities agree that the vesicles grow from the chorionic villi There is no new formation, but excessive and erratic development Mettenheimer. Paget, Barnes, Virchow and others, concur in this Whether the change is the cause or the consequence of the death of the embryo is unsettled It may be some innate morbid condition of the ovum, or some acquired defect Dr Hewitt thinks that the starting point of the abnormality is the death of the fœtus rather than this latter is the result of the

degeneration

Leishman points out that the period within which degeneration of the chorion villi may originate does not extend probably beyond the tenth week, that and multiplication of the villi Later on when blood vessels have occupied the bulk of the villi this kind of degeneration seems incapable of formation probabilities therefore are in favor of the formation taking place in the first chorion or vitelline membrane

Normally, only those villi that correspond to the placenta develop progressively, but if a pathological condition supervenes very early in pregnancy, they all proliferate and become hyperplastic Abortion tioned this several years ago usually follows, but it may happen that the placenta develops normally, only a certain group of villi betion of the cotyledons may be affected

In any case the affection begins as a multiplication of nuclei and cells

Whether simple hyperplasia or a hydatid state rein the parenchyma of the villi, but they have no Jakobson (U H f G u f Bb 13, p 122) relation to the development of the vesicular mole deny that some cells may disappear, or may undergo the peritoneum a fatty change, but they often persist in great num-

Moles of all kinds are covered by a thick mem- bers, and the principal accumulation is relatively brane, which is in immediate contact with the uterus, large, the tissue becomes cystic in appearance and which is nothing but the decidua It has been Where the fibrinous portions are in excess, a simple

Thus these tumors are formed A villus whose Cazeau, M Velpeau was the first to discover that the normal diameter may be hardly half a line, may be dilated to half an inch or more The larger they get the more characteristic they become of mucoid tissue They become clear, transparent, and gelatiniform They contain a ropy liquid which gives the reactions of mucin

The vesicular appearance depends upon the deli-

cacy of the liquid-filled tissue

This development has nothing to do with the vessels, but if it occurs late in pregnancy, the vesicles cimens show both Mettenheimer thinks that on the may become the seat of an extremely rich capillary plexus But vessels are usually absent, at least in eggs coming from the first month, and dropsy of the amnion and atrophy and death of the fœtus occurs in consequence of the disease which cuts off the circulation (Charpentier) Hence, the different descriptions given by authors, and the three kinds of hydatid mole, they are only degrees of one and the same lesion, varying from a simple faulty conformation to complete destruction of the fœtus and the cord

The theories concerning the vesicular mole may be summed up as Duchamp says, in the following propositions I The vesicular-mole is entirely independent of pregnancy 2 The vesicular mole increases under the influence of pregnancy, but is not due to a disease of the egg 3 The vesicular mole is due to a change in the product of conception, from a alteration of the vascular wall (Cruveillier), b alteration of the lymphatic vessels, c dropsy of the chorinal villi (Robin, Cayla), d Myxomatous de-generation (Virchow and the Germans, Ercolani, being the period of greatest activity in the growth Damaschino, Cornil, Ranvier, Hirtzmann, 1874, Jo-Of these the theory of Virchow is sephson, 1879) the accepted one, for the following reasons r The normal villus contains mucoid tissue, it is not astonishing that it should hypertrophy 2 The vesicular fluid contains mucin According to Gscheidlen, it is composed of chloride of sodium, 3 34, phosphoric acid, 0 74, albumin, 6 12, mucin, 2 94, salts, 6 25

Cases are on record in which a repetition follow each other in the one case, Dr McClintock men-Again in some cases a cotyledon of the placenta may undergo such a change and the child be born at maturity alive, but generally coming hydatid Usually, however, the affection is it is carried until labor and then delivered dead situated just at the placental site, though only a por- Such cases are recorded by Hunter (Lancet, 1846, p. 434, vol 1), Krueger, Virchow (Krankhafte Geschwülste, Bd 1, p 405), Martin, Conche et Totan, Vesicular mole can also be carned at Breus, etc the same time with a healthy child, as a twin which sults, it is very common to find the isolated vesicu- is born alive (Viaidel, Boivin, etc), and again there lated cells which Virchow has designated physali- may be extra- as well as intra-uterine moles, as well phores They are found in the epithelium as well as as double extra-uterine molar pregnancy described by

Barnes relates a case in which the vesicular mole The morbid process corresponds to that described as was so intimately connected with the walls of the the mucoid degeneration of cells Virchow does not uterus that the vesicles penetrated the wall even to

Schræder refers to a case by Volkmann, and one

by Jarotsky and Waldeyer in which this occurred The vesicular mole belongs to a class of pathological products known as myxomata (Virchow, Cornil, Ranvier, Malassez and de Sinéty, have demonstrated the identity of the vesicular mole with myxomata of other regions

An analogous degeneration of the placenta has been described by Virchow and Hildebrandt as "fibrous myxoma" of the placenta Schreeder quotes cases of "diffuse my coma" of the placenta by Breslau, Eberth, Spaeth and Wedl

A case of myxoma, or hyperplasia of the choronic villi, is related by Dr Sinclair, in Vol 1, of the Publications of the Massachusetts Medical Society

Different synonyms are Hydatid, or vesicular mole, cystic degeneration of the chorion and placenta, dropsy of chorional villi, myxoma of the placenta

TREATMENT —The treatment of all forms of molar pregnancies consists in the complete removal, whenever practical, of all the diseased tissue The special treatment is of the hæmorrhage General measures and expectant treatment if slight, tamponning if it The expulsion of a few vesicles during the pregnancy does not affect the treatment It is a common thing to recommend oxytocics, preferably ergot, but if this fails to insure the expulsion of the life mass, recoure must be had to other methods We can scoop out all we can reach with our hands, this implies a dilated or dilatable os, and it will be fortunate if we meet with this If not, dilatation will studious, thoughtful practical physician, accomplishes

be necessary, either by the finger or by means of tents, or Barnes' bags A very useful contrivance used in the removal of the fleshy mole is the Beecher forceps, termed by him a "New Abortion and Placenta Forceps" A description can be found in the Medical News, 1883, xlii, 259 The advantages are It is adapted to the removal of the fœtus in abortion, and the placenta, moles, etc, taking hold of a larger portion at a time without in the least imperilling the mother's parts Besides what may be caught in the jaws, if any portion of the mass extend beyond and between the blades behind the shoulders, they are also held without being crushed through, as would be the case in the Bond instrument, with its closely approximate blades, and greater purchase is given upon the mass The fenestrum allows a protrusion through it, and prevents the crushing through the placenta without the ability to remove a portion of the mass other than in shreds It can also be used as a dilator

In some cases the moles adhere to the uterine wall as firmly as a placenta glued by fibrinous deposits In such cases a curette is necessary If the diseased tissues be not removed entirely the portions remain ing may give rise to grave and exhausting discharges or the recurrence as before mentioned

It is also important to remember in this connection that twin pregnancies may occur in which vesicular degeneration affects the membranes of but one It is well, therefore, to bear in mind the pos sibility of this, and that the sound ovum may develop to full development

Even after evacuating the uterus there may be a good deal of hæmorrhage If so, repeat ergot, use abdominal pressure, and give iced drinks, etc The slow convalescence may be hastened with iron, nu, quinine, nutritious food, wines, etc., as the case may indicate

PEROXIDE OF HYDROGEN AS A REMEDIAL AGENT Read before the St Louis Medical Society, February 4, 1888

BY I N LOVE, MD,

CONSULTING 1 HISICIAN TO THE CITY HOSPITAL, ST LOUIS

I am aware that there is a disposition upon the part of some workers in the profession to decry the merits of those whose efforts tend in the direction of therapeutic investigation, and the application of reme dies to the relief of disease, the rather appreciating pathological research and the study of the phenomena of disease

Fully recognizing the importance of closely and carefully scrutinizing the anatomical, physiological and pathological panorama that may be presented to our view, I cannot refrain from suggesting that after all the main object to be attained is the relief of suffering and the prolongation and saving of human The most profound pathologist would be powerless for good did he not have as an ally the delver among drugs searching for the means of mastering the microbes which he has discovered, and the

substantial success who promptly applies the knowl edge gained by both workers, and all are co laborers aiding the securement of that grand millenium when man will pass from the cradle to his second infancy without the shadow of suffering or a thought of disease

familiarity with the make-up and mode of action of mentation these medical and surgical tools is essential to their

graceful and efficient use

Hydrogen," the formula of which is H.O., and which acids to peroxide of barium Meissner, in 1863, proved its presence in the rainwater collected during thunder storms, and this has been corroborated by test of its value Schonbein, Struve and others The usual prepara- knowledge upon this subject, I herewith present the tion of a solution of peroxide of hydrogen depends following cases upon the decomposition of barium peroxide by hydrocloric acid (carbonic or hydrofluoric acid may) be used) in the presence of ice cold water, and the precipitation of the newly formed barium chloride by means of sulphate of silver Such solutions usually contain about 3 to 5 per cent of the peroxide, and are concentrated by freezing, the last portions of water being evaporated in vacuo over sulphunc acid at a temperature not exceeding 68° F In this form it is a colorless, transparent, syrupy mitted to get out of bed. At this time diphtheria liquid, with a specific gravity of 1 452, does not congeal at 22° below zero (F), volatilizing slowly and without decomposition at the ordinary temperature It is decomposed when exposed to the sunlight, or when heated or brought into contact with charcoal, silver, gold, the platinum metals, the oxides of maganese, alkalies and other compounds concentrated form the peroxide, if brought under the conditions favorable, may decompose with explosive violence, and in the presence of the oxides of the metals mentioned they are reduced to the metallic state

Many other bodies act less energetically or are oxidized Litmus and tumeric paper are gradually bleached, and the skin may be turned white by its application, accompanied by itching In the strength to which I am now referring it is without odor and has a harsh and bitter taste, soluble in water in all proportions, which solutions are decomposed by the same agents as the pure compounds, but less vio They are made more permanent by adding a small amount of mineral acid

The commercial peroxide of hydrogen is a 3 per comforts cent aqueous solution, and is prepared on a large scale for the bleaching of animal products such as feathers, hair, silk, bone, etc It is known as "ten of symptoms volume peroxide of hydrogen," owing to the fact

the greatest amount of good and secures the most amount of sulphuric acid, and afterwards a standardized solution of potassium permanganate as long as the latter is decolorized From its very nature this agent should be a powerful antiseptic and a destrover of microbes, anything which accomplishes oxidation as rapidly, if it can be applied safely, must be an excellent application to purulent surfaces for its cleans-Huxley has said that an exhaustive study of drugs ing effect. It has been administered internally for on the part of physicians, was not necessary to their diabetes, but without success Its recommendation proper application to the cure of disease any more for some forms of atonic dyspepsia, would seem to than a complete knowledge of the manufacture of be reasonable, since we know that condition to be surgical instruments was necessary to their suc- frequently due to a catarrh of the gastric mucus surcessful use by the surgeon, however, a practical face accompanied by excessive secretion and fer-

I find there is considerable variation in the effectiveness of solutions coming from different drug The medicament to which I propose to direct stores, this may be due to a failure to protect it from your attention in this paper is the "Peroxide of the sunlight. It should be kept in opaque bottles at I have secured uni a temperature not above 77° was discovered in 1818 by Thenard, by adding dilute form satisfaction from the solution manufactured by the G Malinckrodt Chemical Co of St Louis

> The clinical application of a remedy is the best As a contribution to the fund of

Scarlet Fever and Diphtheria -R H, aged 4 years, an unusually intelligent and interesting boy, developed scarlet fever Dec 22, 1887 nounced case, temperature vibrating for several days from 102° to 104°, throat quite sore, some disposition to ulceration upon both tonsils. Within a week symptoms much modified, temperature ranging in the neighborhood of 100°, where it remained for four days, child being quite playful but not perbecame a complication, involving the pharyix and The secretions from all the the nasal passages mucus surfaces were very profuse and purulent in character, and suffocation at times seemed imminent from its accumulation, and the odor was extremely offensive to the patient as well as the attendants well organized fibrinous exudation appeared over the surface of the tonsils well forward to the palate, and upward to the posterior nares The submaxilary and sublingual glands were much enlarged and en-Wherever a mucus surface was visible, if not covered with diphtheria membrane, it was violently inflamed nearly to the point of ulceration, and exuding a purulent and almost disgusting discharge Temperature ranged in the neighborhood of 104° and 105°, and almost constant paroxysmal cough was present, due to the general irritation, and accumulated secretions, and at times a marked asthma was present, owing to reflex irritation, dependent upon the inflammation of the posterior nares general conditions were alarming, the child being almost in a state of frenzy, owing to his many dis-I shall not give in detail the notes of the case, as I only cite it as an illustration of the value of a particular remedy to relieve a particular senes

Having been using the peroxide of hydrogen in that it yields about ten volumes of active oxygen various strengths for some months as a purifying and which may be estimated by adding a sufficient stimulating wash for purulent ulcers, sinuses, and fistulæ, as well as diphtheria, I concluded to use it as management of no disease, in my judgment, is it so an application in this case. Diluting it with one necessary for the attendant to be ever on the alert part to two of water for application to the nasal as in diphtneria. He should sleep on his arms, so passages by means of a syringe, and using it in its to speak, with one eye open, anticipate his enemy purity by means of probang and absorbent cotton to rather than run the risk of a surprise Well supplied the pharny the pus, and accumulated mucus cleaned out from just enough," and possess an abiding faith in its effi all the surfaces as if by magic bright little hero, and, though semi delirious, he course with remedial agents that we do with friends, helped materially in its application, and also in the study them, try them, weigh them in the balance thorthe removal of the oxidized purulent matter nasal passages, front and back, were soon cleared trust them out, the fauces as well were kept in a comparatively they prove faithful clean condition A good opportunity was now pre- be presented, accept it if it stand the test and prove sented for applying the solution in its purity to the worthy In short, let us not drop an old friend for a membrane direct, and the disintegration of the same new unless the first prove false and the second give was accomplished after repeated application in a evidence of virtue. As an adjuvant in arresting the very decided manner in contact with organic matter, a marked effervescence | the peroxide of hydrogen will stand the test of time and bubbling ensued, and a breaking down of the accumulation or exudation and throwing off of the have applied the peroxide of hydrogen in strengths The beneficial effect of the applicasame occurred cation was apparent, all the distressing symptoms were much abated, and within three or four days One thing quite noticeable they had passed away was, the fact that the constant spasmodic cough subsided after the removal of the purulent secretions from the nasal passages

The success in this case was similar to that in six other cases, and I quote this one as illustrating the class, not desiring to indulge in repetition by reporting them all This child was in a most dangerous condition for many days and nights, and I do not claim that the peroxide of hydrogen saved him, but it certainly helped to do it, in that it enabled me to combat the local poison, acting as an antiseptic, a germicide applied to the fauces in the same manner A free of the most pronounced character, a remover of purulent septic matter and offensive odors, aiding in the conservation of comfort to patient and attendants

Constitutional measures were, of course, never lost sight of, constant attention being directed to excretion, sedation stimulation and nutrition Other local measures were of course used, the peroxide serving as irritating germ, and possibly the agent used above a means of "clearing the track" for the application killed the microbe of soothing and healing ointments to the nasal passages and the spraying of all the surfaces with Listerine and other remedies as indicated

En passant at this point permit me to remark that I have no patience with the practitioner who permits himself to be overcome by a physical, mental and scientific inertia, so that he can sit idly by and trust If one's house entirely to the vis medicatrix natur a is on fire and he trusts to nature instead of turning on the hose, the chances are that he will sleep on the The "theracommons unless a friend takes him in peutic nihilist" should change his calling The practitioner with no faith in physic, who, like Solomon, cries out "All is vanity," gives evidence that he has mistaken his vocation, or, like Solomon, indicates What would one that it is time for him to abdicate think of a soldier who was ever decrying the ments of his cause and gun? Either that he has a poor cause and an inefficient gun, or does not understand trouble, but would suggest from the manner of its the one nor know how to use the other In the action that it is worthy of trial

I soon had the satisfaction of seeing with ammunition, ready to use it "not too much but The child was a cacy In wrestling with disease let us pursue the The oughly, and if not found wanting adopt them and Then let us stick to them as long as If they fail us and a better one Wherever the solution came destructive tendency of diphtheria I am persuaded that

Purulent Ozana and Chronic Nasal Catarih-I varying from 1 part to 3 or 6 of water in four cases of the above character during the past month favorable reports have been given me, enough so to justify me in considering it of great value in this A sufficient time has not elapsed to enable trouble me to determine whether it will secure a permanent The application was made three times daily

Acute Coryza - The peroxide in the proportion of I to 4 of water was applied freely by means of a syringe through the nostrils, a hard rubber syringe gently throwing about 2 tablespoonfuls into each nostril while the head is thrown backward back through the posterior nares, carrying the completely oxidized mucus secretion with it. It is then sneezing and perfect discharge follows cation is made about once in four hours in the begin ning and less frequently later Three such cases were greatly relieved after first application and cured inside of a day or two It is well known that influ enza, in some cases at least, is dependent upon some

Whooping-cough -In two cases where the paroxysms were frequent and violent I have had great sat isfaction in seeing the frequency and severity much modified by the use of the peroxide of hydrogen (r to 4) twice daily, and the attack was unquestionably cut short

Reflex Asthma -Two cases of reflex asthma intercurrent during an attack of diphtheria and a general catarrhal fever, dependent upon the irritation in the post-nasal space, were promptly relieved after a few applications of the peroxide (1 to 4)

Follicular Tonsillitis - Very satisfactory results were obtained by using the remedy as a gargle (1 to 3) every two or three hours Listerine, callendulæ, tincture of iron and other soothing, stimulating and astringent remedies were used by the atomizer between the intervals

Hay Fever -I have not used the remedy in this

Cancer of the Womb —In this affection I have had great satisfaction in using the peroxide in its purity as a cleanser, deodorizer, and stimulator of healing in that portion of the ulceration probably dependent upon the irritating effect of accumulated purulent The gratification and comfort to patient and attendants secured by the application well repaid One who has never observed the horrible stench in the room of a neglected cancer of the womb can have no conception of the value of the drug in this connection Dr Joseph Grindon, a dermatologist of St Louis, informs me that he has used the agent to remove pigment spots from the skin is the main remedy furnished by dealers to weakminded women for blonding the hair

It is needless for me to continue to cite cases and conditions where the peroxide of hydrogen will prove I think it worthy of trial in gonorrhæa

After a six months' trial of the peroxide of hydrogen, considering the nature of the agent and its effect concluding

I The peroxide of hydrogen is a most efficient means of cleansing purulent surfaces, deep cavities and sinuses, and stimulating the healing process in ulcerating parts

As a destroyer of microbes it is of great value as a local application in diphtheria and scarlet fever,

ozæna, coryza and whooping-cough

3 For the above reasons it should prove of value in gonorrhœa, hay fever, and similar disturbances probably dependent upon specific germs

FACTS IN RELATION TO EMACIATION

Abstract of Paper read before the Medical Society of the District of Columbia

> BY THOMAS TAYLOR, M D, OF WASHINGTON

For several years past I have devoted much of my time to the crystallography of animal fats, and have examined, crystallized and photographed the fats of several hundred animals, and a few vegetable oils In the prosecution of this inquiry I observed inci dentally, that the fats of several monkeys, victims of consumption, when rendered, strained and cooled, at a temperature of about 70° F according to my usual method of treating fats in order to crystallize them, exhibited but a trace of the solid fats, the mass consisted principally of olein From this fact my attention was directed to the consideration of the fat of human beings, subjects of emaciating diseases, from whatever cause I have tested the fats of three con sumptives who were greatly emaciated The fats were crystallized in the usual manner-boiled, strained and cooled, at 70° F - and, when examined, were found to be nearly destitute of solid fats, olein largely predominating

While the cases cited are insufficient data for determining what may be the invariable condition of the worthy of attention, and I propose to continue these and edited by M Apery

researches in order to ascertain whether the condi-If in the animal tions I have stated are constant economy, it can be shown that there is a greater tendency to oxidize the solid fats than the oil, in cases of high temperatures and emaciation, valuable information will be gained

With regard to the composition of fats in general, they consist of three distinct fats, viz olein, palma-These are known as glycerides of tin and stearin the fatty acids oleic, palmatic, and stearic Early chemists applied the term margarin to a substance they believed to be a simple fat, but modern chemistry has demonstrated that this substance is merely It has been a combination of palmatin and stearin demonstrated that the fat of milk and butter contains but a trace of stearin, and that it is composed mostly of palmatin and olem, and it is also stated on high authority, that the fat of man is of similar composition

In my investigations relating to the forms of aniupon purulent matter and bacteria, I feel justified in | mal fat, I have observed that the crystals of human fat have a marked resemblance to crystals of milkbutter, suggesting the importance of the use of milkbutter as the proper form of fat for man, and superior to fats which consist largely of stearin, such as some oleomargarines I have tested

According to modern chemistry stearin requires a temperature of 144° F to melt it, and in each succeeding fusion a still higher temperature is required this reason the common fats cannot be as well adapted for the sick as butter, which melts at blood-heat Therefore I think it might be well to test the value of pure butter as a substitute for other forms of fat now In this case I would in use in cases of emaciation suggest that butter used for this purpose be boiled and strained to remove its casein, the casein of milk frequently proving very indigestible and unbearable to a weak stomach

Milk, the natural food of man, contains all the essential proximate principles necessary to build up a perfectly healthy human being, but the butter fat of milk contains but a small proportion of nitrogenous matter as compared with the milk from which it is made, therefore, butter of itself does not afford sufficient nitrogenous matter to sustain life but for a limited period As it is desirable to make sure that the diet contains a proper amount of nitrogenous matter, in an acceptable form, I recommend the use of peptonized beef, in other words, digested beef, in connection with butter so treated Such a combination would build up the vital tissues

As the solid fats of butter contain a larger amount of carbon than is found in the same amount of oil, the oxidation of these solid fats would contribute more animal heat than would the oxidation of the oil In this process water would be formed, the elimination of which would lower the temperature of the body, thus tending to arrest the destruction of the tissues

The "Revue Médico-Pharmaceutique is the title fats of emaciation, I deem the facts thus far observed, of a new journal recently begun in Constantinople,

MEDICAL PROGRESS.

THE TREATMENT OF WOUNDS BY IODOFORM TAM-PONS — DR F BRAMANN reports (Archiv fur klimische) Chaurgie, Berlin 1887) the results of treatment of wounds in von Bergmann's clinic for some years The gauze employed is sterilized by means of steam at 212°, and after drying may be impregnated with an antiseptic solution. The sterilized gauze is used in cases of trifling operations in small wounds In larger wounds with more profuse secretion, it second time for the application of the sutures was thought best to obtain whatever advantage could be derived from the impregnation with corrosive sublimate, especially as the patients and operators are in the immediate vicinity of an audience coming direct from the anatomical rooms The cotton em-The towels, ployed is of late years merely sterilized gum cloths, sponges, etc., are treated in a like manmetal spools, sterilized by steam, and inclosed in The catgut used for deep stitches metal caskets (stitches of relaxation), and for ligatures, is kept ten to fourteen days in a solution of 4 parts bichloride, those cases in which, for any reason, as great weak-800 of alcohol, 200 distilled water This is frequently ness, or for the stoppage of bleeding from large 800 of alcohol, 200 distilled water The catgut is then changed to an alcoholic sublimate solution of 1 to 800 alcohol and 200 parts of water, and is taken direct from this The preparation of the patient consists in giving full baths, washing the region of operation with soap and water, shaving the part, rubbing the skin with ether, and January, 1888 disinfecting it with from I 1000 to I 200 solution of The instruments are kept in a 3 per During the operacent solution of carbolic acid tion the wound is often irrigated with i 2000 bichlo-In operations in the abdomen, the ride solution pleural cavity, the mouth, rectum and bladder, salicylic acid i 1000, or boric acid i 200 is employed, and at the end of the operation a solution of 10doform in ether is generally used

Next to strict antisepsis, the complete stoppage of bleeding is regarded as the chief agent in procuring

union by first intention

When the wound is dry, and the smallest bleeding vessels have been tied, the suture is applied with or without drainage, but only in those wounds which are considered absolutely antiseptic, and have not been infected through previous suppuration or con-Among the cases tact with unclean materials treated in this manner are included all extirpations of tumors, removals of breasts, amputations, osteoto-

mies, etc In wounds where the bleeding cannot be entirely stopped the formation of a large clot is objectionable, not only on account of the pressure which it may make, as in fractures of the skull, but because of the risk of decomposition and blood poisoning Although such clots may, through absorption and organization into connective tissue, aid in the process of repair, they sometimes remain fluid for long periods, and during that time are a source of danger Therefore, when it is impossible to dry the wound absolutely, or where there is the least suspicion that a nitrogenous diet it is not entirely aseptic, after thorough disinfection milk may be attained, speaking generally, by the use

with 1 1000 bichloride solution and with an ethereal solution of iodoform applied to the wound by means of a syringe, it is loosely packed with strips of iodoform gauze of several feet in length, and three to four inches broad They are applied so that the larger part of each strip lies in the wound, and the ends come out at the angles The sutures were formerly put in at this time, but this has been abandoned on account of the difficulty in keeping them disentangled, and of their adhesion to the iodo-The patient is now anæthetized a tamponed wound is covered with sublimate gauze and cotton and an antiseptic bandage If the secretions make their way through the dressings, the superficial layers are renewed, but the iodoform gauze is allowed to remain undisturbed for two days If it is then removed by gentle traction on the ends hanging out of the wound, the latter is found clean, The silk used in sutures is wound on glass or unirrigated, not reddened, absolutely dry, and it is only very exceptionally that a ligature is required Careful suturing, with or without drainage, has resulted invariably in union by first intention, even in those cases in which, for any reason, as great weakvessels, the tampon has been left in from four to six His report of his results is extremely interestdays ing, includes a large number of important cases, and appears to confirm his estimate of the value of this method -American Journal of the Medical Sciences,

> THE DIET OF NURSING MOTHERS -The influence of the diet upon the function of lactation is a subject of such importance for the rising generation as to warrant frequent investigations by scientific authorities It seems to be one of the evils inherent in a high degree (so-called) of civilization that women, in a large proportion, especially among the upper and middle classes, should suppress and ignore the physiological function of the secretion of milk, and abandon the privilege of nursing their children in a natural way But this being the case, it is desirable that the best The feeding-bottle is but a substitute be provided poor substitute for the mother's breast, and of late there is a tendency to give too diluted a milk. A wetnurse is the best substitute for the mother herself, and a knowledge of the influence of the food upon the composition of milk ought to be widely circu-DR ZALESKI, lated, at least in its chief features Docent in the University of Dorpat, is the latest worker (Berl Klin Wochenschr, Nos 4, 5, 1888) in this subject. He has made careful analyses of the proximate constituents of milk, both in the lower animals and in women, under various conditions of 1 Milk which diet, and his chief conclusions are contains an undue proportion of fat may have a very 2 A highly nitroginjurious effect upon the child enous diet causes a great increase of fat in milk, the same kind of diet lowers the proportion of milksugar, but has very little influence over the other Alcohol exerts the same influence as 3 A proper composition of the constituents

4 The lower animals are subof a proper dietary ject to the same laws as human beings in the above 5 A large proportion of milk is derived, directly or indirectly (that is, by changes in the them, three gall stones the size of marbles blood itself or in glands), from albuminous sources The above conclusions are directly opposed to the views of the laity on the subject. The wet-nurse, as a rule, is a highly privileged being, who must be allowed an unlimited quantity of butcher's meat and will, active exertion is out of the question ably the diet has been previously very plain, and too often the sudden change influences the composition of the milk to the detriment of the child Diarrhœa, of a more or less fatty character, is often the consequence, and Dr Zaleski instances a case in point quiry was made as to the condition of the child services of the wet-nurse had been called into requisi-The latter was a poor girl, whose diet and whole course of life was changed when she became a wet-nurse, and that this injuriously affected the lacteal secretion was proved by the fact that her own child had been far from well since then An ımmediate return to the previous mode of life was ordered for the nurse, with the best results -British Medical Journal, February 11, 1888

OLD RUPTURE OF GALL-BLADDER, ADHESIONS OF LIVER TO COLON AND PELVIS —In Progress, January. 1888, DR Joseph Eastman, of Indianapolis, reports

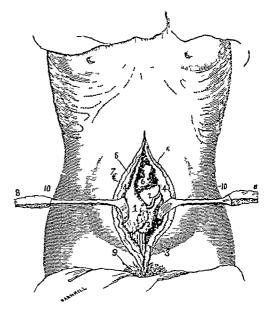

the following case

Mrs W, Chelsea, Ind, sent by Drs Phillipps, of Chelsea, and Sipe, of Orange, with this letter of diagnosis "I Ovarian, (a) solid tumor of ovary rare (b) Would probably be more movable 2 Omental tumor, (a) solid tumors of omentum are almost in variably malignant 3 Kidney, size, shape, mobility, correspond to a displaced Lidney, which I think it is It might be cancer of the kidney, but I do not think there is pain enough for that, so it is excluded Finally, as the diagnosis is not clear, I would advise waiting till fall-watching its growth and other symp-Meanwhile, give general tonics and cheer her REAMY "

Examination Somewhat elongated abdominal tumor a little to right of median line of abdomen Could be outlined fairly well by palpation It was not kidney-shaped, nor scarcely movable gave impression of much thickness Kidney of right side definitely outlined in normal position through Subjective Fourteen years ago had stooped position Contraction and pain increasing till the condition seemed to demand surgical relief

Operation October 18 Incision exposed abdominal organs as shown by 3 in figure A firm cicatricial band held the right lobe of the liver down in the right thac fossa. This was

of the liver and find the ascending colon, adherent to inner border and under surface of liver On separating gut from liver I found, "plastered" between more through wall of bladder and incised the cyst, removing fifty-one more gall stones Gall bladder shrunken and dry I here present them in box, they vary in size from a grain of wheat to tip of thumb Closed incision into gall-bladder with silk, Lembert's a good supply of stout The amount of exercise sutures, to make the closure perfect, there being no usually taken is a gentle saunter at her own sweet gall in bladder. I did not put in a drainage tube, as Prob-the gall had escaped in some way for years through ducts, or else had not been poured into the cyst Having broken up extensive adhesions on surface of liver and bowels, I put a glass drainage tube into the abdominal wound and closed the same around it Nothing of note followed, except that the patient Chemical analysis of a specimen of the milk of a has made a good recovery and is at this date, Decemwet-nurse revealed over 6 per cent of fat, and in- ber 15, seemingly cured. The liver can now be felt It to the right and slightly above the umbilious, its lower appeared that the child was alling ever since the margin at least six inches higher than before the operation

r-Right lobe of liver 22-Bowel adherent to liver 3-Cicatricial band dragging liver downward 44-Peritoneum everted by retract ors 55-Thickness of abdominal parietes 6-Bowel, also adherent to liver 7-Umbilicus 88-Retractors 9-Mons veneris 10 10-Sup crest ilium

Comment -From what information we have, this was a case of formation of gall stones fourteen years ago, with enlargement and rupture of gall-bladder, causing local peritonitis, with resulting adhesions between liver and ascending colon The alternate "spells of bilious colic," since then has felt dragging distension and relaxation of this bowel may have pains in abdomen, causing her to assume a somewhat increased the extent of the adhesions downward and inward, until the inflammatory process firmly anchored the liver to the pelvis, by the formation of My usual aseptic precau-the dense band of tissue represented in the figure

In the Transactions of the Indiana State Society, 1879, Dr Kemper, of Muncie, reports a case in some severed, thus enabling me to raise the inner margin respects similar, except in the important particular that Nature formed a bihary fistula, which cured the one generally used, for, the patient being in the ob In this same valuable contribution to the literature of the subject, Dr Kemper collects a number of cases

REMOVAL OF GALL-STONES -In Progress, Jan, 1888. DR EASTMAN also reported the following case Mrs H, set 59, living in Delaware county, Ind, near De Soto, consulted Dr Bunch, the family physician, who not being positive of his diagnosis, called Dr Kemper, of Muncie, who diagnosed a distended gallbladder, and was positive it contained gall-stones November 10, at patient's home, assisted by Drs Kemper, Bunch, Wymans and Boyden, I opened the abdomen in the median line, making an incision some five inches in length, lifted the gall-bladder up into the wound and incised it

A half-pint of inspissated gall and mucus passed Introducing my finger I could feel two gall stones the size of marbles, removing these I detected still another lodged in the duct, which was with some difficulty squeezed up into the bladder by pinching the duct below the stone It was removed, the bladder stitched to peritoneal layer to abdominal wound, and the abdominal incision closed around a small rubber drainage tube, which was lest in the gall-There was a free discharge of bladder for drainage bloody mucous through this tube for five days or When this had become less the tube was Patient recovered removed

TREATMENT OF RETAINED PLACENTA -DR LANE describes the method pursued at the Rotunda Ma-When the placenta is ternity, Dublin, as follows adherent I believe the proper treatment is to pass the hand or fingers into the uterus and detach it, although I have been informed that some Continental obstetricians allow the placenta in such cases to remain for even a month after delivery (unless there is hæmorrhage or symptoms of septicæmia), especially in the cases where the patients have not come to I consider, however, that if the optheir full time erator's hands be not perfectly aseptic, this is the most dangerous of all operations met with in midwifery practice, except the Cæsarean section has been recommended by some authorities to keep the fingers inside the membranes during the operation, but there are many cases met with where, owing to the friable nature of the placenta, necessitating the removal of small pieces at a time, this is impossi-Should there be any septic infection about the hand, and especially about the nails, the usual seat of such poison, I failed to see how such a patient can escape becoming infected, for it is analogous to vaccination, except that virulent poison is substituted for healthy lymph, and with unfortunately greater likelihood of its taking effect, owing probably to the prolonged contact The uterus, except where it has already been douched out with the hope of getting the placenta away, as I have already mentioned, is always douched with antiseptic solution prior to introducing the hand Although the left hand is recommended by many as being smaller and corresponding more with the pelvic curve, the right hand is the Annals of Surgery, Jan 1, 1888

stetrical position usual in this country, the fundus of the uterus can be better and more easily supported by the left hand (the operator standing at the patient's Nor can an assistant, no matter how ex back) perienced he may be, support the uterus so satisfactorily as the operator himself, who knows the exact part of the uterus requiring pressure as to bring that particular part of the uterine wall nearer to the introduced hand, and who is able to remove it to some other part the moment required

An anaesthetic, usually chloroform, in order that, if necessary, the hand may be passed in a second time where doubt exists whether all the placental tis sue has been detached, for if the patient be perfectly conscious of what is being done, the operator must be very resolute to be able to withstand her solicita tion not to pass the hand a second time, and I con sider that, once the hand is introduced, the operation should be persevered in to entire completion When satisfied on this point, the uterus should be again douched out with antiseptic solution -Practitioner, December, 1887

PICRONITRATF OF AMMONIA IN MALARIAL FEVER -In the Bulgarian Meditzinsko Spisanië, Nos 31 and 33, 1887, DR A GOLOVINA, lady physician to the Varna Town Hospital, writes that, at the suggestion of Professor Fr Goll, of Zurich, she tried picronitrate of ammonia, in 3-centigram pills, four times a day, in seven cases of malarial fever of quotidian type In five the paroxysm ceased to recur (in one case from the second day of the picronitrate treatment, in three cases from the third day, and in one from the Three of the successful cases were of recent sixth) origin, and two fairly old The quinine treatment had been previously tried in three of them (including the inveterate ones) without result In a sixth pa tient, however-a lad with quotidian fever of two and a half months' standing—a seven days' course of the picronitrate utterly failed to arrest the paroxysms, the latter subsequently disappearing in two days under quinine (50 centigrams twice daily) nitrate apparently gave negative results also in Dr Golovina's seventh case No unpleasant secondary effects were ever observed -British Medical Journal, February 11, 1888

DRAINAGE AND PRIMARY UNION -CHENIEUX, of Limoges, in an article on this subject, draws the fol lowing conclusions

1 Drainage is prejudicial to primary union of

wounds 2 Wounds whose edges are perfectly apposed and made aseptic should heal by primary union

3 In operations such as ovariotomy and hysterectomy, in which ligatures must be concealed and in which there are large bleeding surfaces, drainage seems to be rather hurtful than useful

4 Exuded fluids seem to constitute reserve fluids, and to be reabsorbed into the system in case of drainage they are lost, and become poisoned by microbes - Revue de Chirurgie, November, 1886 -

Journal of the American Medical Association PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All com munications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE INCLUDING POSTAGE PER ANNUM, IN ADVANCE \$5 cc SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order drawn to the order of the under signed When neither is accessible, remittances may be made at the risk of the publishers by forwarding in REGISTERED letters. Address

SANITARY ARRANGEMENTS OF LARGE COMMUNITIES

The Inaugural Address of the President of the Liverpool Medical Institution at the opening of the session of 1887-88, delivered by DR J BIRKBECK NEVINS, and published in the Liverpool Medico-Chirurgical Journal for January, 1888, is one of exceptional interest It is an exhaustive review of the sanitary conditions of the Hebrew camp in the desert, and of the cities of Manchester, Edinburgh and Liv-The Mosaic regulations for the health of the camp in the desert after the Hebrews left Egypt are, or should be, familiar to all, and the only reference that we will make to Dr Nevins' discussion of them will be to quote the following "All dead bodies also were to be buried entirely outside the camp, a sanitary regulation in advance of our own by thousands of years, for we have not even yet entirely ceased to bury our dead in the midst of our population, and thus to pollute both our air and water We have not even attained to the wisdom which buried the dead in porous cloths, which favored the rapid oxygenation and thereby the removal of the body "

In regard to the sanitary regulations of Manchester there are several striking features The city is situated on a level plain, that is skirted within 20 or 30 miles by a circle of hills The rivers flowing by the city are rendered so impure by manufactories that the water is unfit for personal use, and the city is at such a distance from the sea that the removal of its liquid refuse is a difficult problem, as was that of removing the solid refuse from the streets and dwell

water-closets Each house has a back yard, at the far end of which is an ash-pit and a privy, with a back door communicating with the roadway between the backs of houses on adjacent streets The night-men of the city sanitary force have access to the ashpits and privies through the back door The authorities provide two pans for each house-one for ashes, vegetable waste, and other solid matters, and the other a carefully made waterproof iron pan, that is put under the seat of the privy, and removed once a The water-closets empty into the week or oftener sewers, and liquid slops from the houses without closets are poured into the sinks or into the gutters, but all solid excreta are received by the pan often as necessary a covered wagon, long and airtight at the top, and with sides that fall down by hinges, is sent to collect these pans Sawdust and carbolic acid are placed upon the bottom of the wagon, and the pan is taken from the privy seat through the door at the back, and then covered by an hermetically tight lid, this lid is so tight, and the wagons so fairly air-tight, that only a slight odor, chiefly of carbolic acid, is perceived as they go through the streets The wagons are driven into the top story of what may be called a purifying house, and the contents of the pans are emptied into a hopper, and are finally converted into a dry powder, which is readily sold for \$15 a ton as manure city guarantees that this shall contain a specified quantity of organic nitrogen and phosphates, to insure which the bones from slaughter-houses and other places are used and mixed with the powder

Here, then, is a great city converting its solid excreta into a saleable manure, by a process carried on with such care and skill that the odor in the works is not oppressive nor injurious to health, and can scarcely be detected outside the works The street sweepings are disposed of by being used to absorb liquid manure and sewage, so as to make a portable article

In Manchester, also, the ashes and other dry and innocuous rubbish are made into a saleable article, after being burned, the residue being a mass of clinkers, these contain so much mineral and siliceous material that they are valuable as a material for making mortar for building purposes, and also for making Diseased meat, dead animals, and spoilt or condemned fish are also utilized by being made into oil (used for lubricating machinery and for making soap), while the residue is turned into manure Manchester has not yet solved the sewage problem, but is making preparations for conveying it to a place ings The city contains 66,000 privies and 11,000 five miles distant, where it will be purified by precipitation with lime, and the sewage water will then that it borders upon the sea, that water-closets are be discharged into the Irwell

From a sanitary point of view Edinburgh is exceptionally interesting, partly because the city consists of three portions of about equal size, that differ so much as to require different sanitary meas ures, and partly because a very important experiment in sanitation has been carried on in it for more than a century The central and most elevated portion consists almost entirely of old houses, so constructed that sanitary improvements in them are practically out of the question In this portion 8,804 houses have water closets, and 8,664 have Nearly all the houses have a sink for the liquid excreta and waste, but the pail system is in full operation, the pails and ash pans, and other receptacles for dry rubbish being removed by nightmen The night-carts are open, but made as watertight as possible So many ashes and dry street sweepings are collected on the rounds that the pails are emptied directly into the wagons, and a practically dry load is taken to the stations for removal into In the lower parts of the city the the country scavengers' carts remove the dirt or refuse in the roadway, the walks are washed and some slaked lime is sprinkled on them This is taken up by the In the new parts of the city the waterclosets are almost universal But in the final disposal of its solid refuse Edinburgh has more trouble than Manchester, since its value when offered for sale by the city is only a few cents a ton sewage of the city, however, is abundantly utilized for direct fertilization

In Edinburgh there is compulsory notification of infectious diseases, which is liberally paid for, and compulsory removal of the cases to hospital if the medical attendant desires the cases to be so removed The system works well, the compulsory removals being especially welcomed by the hotel and lodginghouse keepers, because the medical officer has the room disinfected immediately, and then gives a The effect of this system has clean bill of health been seen on both the general and the zymotic mortality for a period of six years, commencing with 1869, the average general death-rate per 1,000 was 25 85, average zymotic mortality 17 98, for a period of six years, commencing with 1879, the average general death-rate was 19 04 per 1,000, a reduction of 25 per cent per 1,000 average zymotic mortality 11 9, a reduction of 33 33 per cent per 1000

almost universal, and privies scarcely to be found, and that all the sewage of the city is carried out to Other features are good water-supply, prompt removal of unsanitary property, improvement of ventilation by opening up courts, increased hospital provision, the scavenging of the streets, and the public urinals From 1850 to 1885 the death rate fell from 36 to 23 7 per 1,000, which is a saving of about 7,000 deaths annually Practically none of the solid refuse of the city is utilized in the manner adopted in Manchester The city has two dumping steamers that carry the refuse out to sea about two hours before high water Combustible materials, such as matrasses, etc, are burned, and the ashes Street sweepings are sent into the country and sold as manure Until fifteen years ago the dry refuse of the city was used for filling in and making This was objected to by citizens, and the ground corporation ceased to employ the cinder-waste, etc, for this purpose, though a thorough investigation made by Drs Parkes and Burdon Sanders showed that after two or three years such ground might be safely used for building purposes, without any fears Their report has been conof sanitary evil results firmed by the reports of the Medical Officer of Health of the city, and by those of the Health Officer of Manchester

The "trough closet" system is also a feature of the sanitary arrangement of Liverpool, every court, in proportion to the number of its houses, being sup-They are long deep troughs plied with one or more made of slate or some such non-absorbent material, and are placed under the seat of every closet troughs are filled about a foot deep with water from a tap out of control of the occupants of the court, but which is accessible to the night-man, who can dump the whole contents into the sewer, and then thoroughly cleanse the trough

The 249 miles of sewers of Liverpool are ventilated by grates, 4338 in number, placed in the streets at intervals of about 80 yards, the clear apertures of the grates being never less than 63 sq inches In addition to grates create no nuisance whatever the street-drain gratings the court-drains are ventilated by ventilating shafts 6 inches in diameter Every court is drained, and when there is no thoroughfare through the court the drain is closed at the top of the court

In cases of infectious disease in Liverpool the bedding and such articles as cannot be disinfected by washing are removed, exposed to a high tempera-The special sanitary features of Liverpool are ture (2120-2200), and returned in a vehicle that is never used for conveying anything previous to disin fection Infected rooms are disinfected by the burning of sulphur

Almost in the centre of Liverpool is a large abattoir Dr Nevins states, from personal inspection that no nuisance arises from the city abattoirs The manure and offal are mixed with dry ashes and The blood-clot is dried with sent into the country the smallest possible delay, and before any trace of decomposition has set in The small intestines of the animals are converted on the grounds into what is usually called catgut, and by a process that is comparatively free from smell or filth

Dividing the ten years 1874-1883 into two periods of five years, we find that the deaths from fevers fell from an average of 23 in the first five to 10 8 in the second five years, and the deaths from diarrhœa from 32 to 21 4, showing a marked decline in the diseases most likely to be produced by nuisances

UNETHICAL USE OF PHYSICIANS' NAMES

In the Department of Correspondence we publish this week a letter from Dr Charles W Kollock, of Charleston, S C, in which he makes a complaint that is perfectly just. With his letter he sent a column advertisement from the Charleston News and Courier, showing how the names of reputable physicians can get into strange places and very bad company this particular case these names are sandwiched between those of several prominent politicians and not a few so called "pulpit orators" There are in all 21 names of Chicago physicians, representing the various colleges and both the regular and irregular schools

With the clergymen and politicians that are afflicted with the apparently incurable itch of seeing their names in print, we have nothing to do except to say that if they are anxious to make a display of their ignorance they should do so in some way that will not tend to injure other and still more ignorant people that look up to them Even an Ex-President of the United States-and there is only one-stopped raising pullets long enough to give "Dr Morris Bernhardt" and "Dr Louis A Matthez" a recommendation in the following ungrammatical language "He is entitled to confidence As an optician I recommend him" The names of governors are "thick as leaves ın Vallambrosa"

The profession in Illinois have been trying for years to get rid of quacks and irregular practitioners But is it just that Chicago physicians should give

prey upon the people and the physicians of the States that have no laws regulating practice Dr Kollock is a young man, but recently embarked in his practice and specialty, and it is in the highest degree unjust to him-and to every other practitioner-that medical men are so careless in giving their names to every pretender that comes into their offices with an auto-The very fact that a man comes into graph album a physiciar's office and asks for his name is circumstantial evidence that he is going to use that name improperly To an honest man the name of another man is, as a rule, not worth carrying around sufficient reasons we think it best not to publish the hst of names sent us but the time may come, if such things continue, when such a publication would be but an act of justice to the profession at large

LEA BROTHERS & Co, of Philadelphia announce the early publication of a very important Clinical Atlas of Venereal and Skin Diseases, including Diagnosis, Prognosis and Treatment, by Professor Robert W Taylor, M D, of New York The work is to be issued in eight parts, aggregating 58 large folio chromolithographic plates, and containing about 200 figures. It is to be published by subscription

THOMAS B LESTER, M D, died at his home, Kansas City, Mo, Feb 24 1888 He was one of the oldest and most prominent members of the profession in that part of the State He became a member of the American Medical Association in 1872, and once served as one of the Vice-Presidents

SOCIETY PROCEEDINGS.

ST LOUIS MEDICAL SOCIETY

Stated Meeting, January 21, 1888 THE PRESIDENT, Y H BOND, M D IN THE CHAIR. DR MEISENBACH presented a specimen of

ATRESIA ANI

The male child from which this specimen was taken was three days old before it was noticed that there was an imperforate anus and that the child did not pass the contents of the bowel, that careful examination of the genitals of the child which should always be made having been omitted When I first saw the I found that the exchild it was three days old tremities were livid, the skin was jaundiced, and the child was vomiting a Jellowish-white fluid, there was them recommendations so that they may go off and no meconium, I think, but simply the contents of the stomach the abdomen was very much swollen, slightly tympa- the patient would not be better dead than to have the nitic. I found the perineum was very rigid. There rectum either in the lumbar or inguinal region? Of was no sign whatever of a rectal bulb, and I came to course, if this child had been seen at an early day, the conclusion that the bulb or rectal pouch must be within a few hours after birth, either one or the other very high np, otherwise there must have been some of the two latter operations might have been successindication to the sense of touch of its existence found in the raphé, at the site where the anus should the operation was concerned, but the question is have been, a slight protuberance, which is very nicely shown in the specimen here I told the mother that, on account of the length of time that had elapsed, the condition of the child and the symptoms, in my opinion, if the operation were performed, the child would probably die, and that I would not operate The father opposed the without the father's consent operation upon the grounds I have stated, that the child was then almost in the throes of death here the rectal bulb, a section of the perineum, the bladder and one-half of the pelvis of the child The rectal bulb terminates fully one inch above the perineum I left the meconium in, to show the relations of the parts more clearly

I found that the view which I had entertained that the rectal bulb must necessarily terminate very far have reached it through either the inguinal or lumabove the perineum was correct tissue does not show any development of the rectum been decided before the operation at all, it shows simply a fibrous and connective tissue development in which this malformation may occur very high or it may be a mere septum barring the If there is simply a thin septum of perineum over may be various degrees of the distance from the perineum to the bulb of the rectum Part of the colon may be absent as far as the ileo-caecal valve, and had several such cases In one case I made an inthere may be merely a cord representing the colon

way of correcting the malformation is to cut down through the permeum and attempt to reestablish the the part so that there was no trouble to make an prima via, and in some cases this is possible, and in those cases where the termination of the rectal bulb is superficial that is the operation to perform If you remember the anatomy of the infant pelvis, you will recall that the area of the perineum is very limited, we will find by measurement in the newborn that the nection, however fine, with the urethra or neck of the distance from one tuberosity of the ischium to the bladder terior diameter of the perineum from the arch of the the vagina, bladder, or into the urethra or ureters other is not over 1 inch, and also that the antero-pospubes to the tip of the coccyx is also not more than I operation is a difficult procedure, and especially so in upward toward the kidney, so that where there is but a case like this, the bowel being practically almost one kidney, there may be two ureters, one to one out of reach, so much so that it may be impossible to kidney, the other extending from the bladder a contwo operations then would be by opening the rectum should be, so the anus is formed by an invagination, in the inguinal region or in the lumbar region is not possible to establish the prima via through the ing the lower end of the bowel above permeum, resort is had to one of the other opera-It has also been attempted, after performing the operation in the inguinal region or in the lumbar region, after the patulency of the canal has been es- in the sinus urogenitalis neum, but this has proven to be a very dangerous thoroughly, and as far as ordinary evidences go, there procedure Cases in which it has been attempted is no opening communicating from the rectum to the

Upon a careful examination I found that have proved fatal The practical question is, whether I fully accomplished as far as the life of the patient or whether it would have been a practical operation as far as the patient was concerned, when you take the conveniences of life into consideration I believe a patient is better is an open question dead than to have an anus in the lumbar region or in the groin, whether that patient be young or old course this is probably not the right view to take from the standpoint of the surgeon, but I think that is the proper view to entertain from a moral standpoint

If you had seen this child in DR EDW BORCK the beginning, what kind of an operation would you

have performed in this case?

I should probably have at-DR MEISENBACH tempted to find the gut through the permeum If satisfied that I could not accomplish this I would The intervening bar region Of course that point would not have

The pathological specimen is Dr Edw Borck There are various stages or forms interesting and instructive, especially to the surgeon It may be who takes an interest in congenital malformations It may be very readily severed, or there the rectum, it is a very simple matter, but if the bulb of the rectum is high up and you cannot pull it down, the operation is much more difficult I have cision until I reached the rectum, and then operated The practical point that I wish to demonstrate is no further for three days, simply keeping the wound in regard to an operation The first and most natural open with sponges On the third day after I found that the meconium had come down and distended opening and stitch the end of the gut to the skin, thus making an opening In that case the child recovered without any bad symptoms

There is one point that should be ex-DR DEAN amined still more closely to see if there is any conwithout there being an exit somewhere, either into With an area of 1 inch by 1 inch, the neys downward to the bladder, but from the bladder If it involution or growing in of the epiblast upward, meetof the mesoblast is to unite in advance of the epi-If the splanchnopleure closes before the somatopleure, the opening may remain in the cloaca or

I distended the bowel pretty

been able to express from it some of the meconium and fluid I found no evidences of exudation out the parts I sewed that up carefully and then put pressure upon the contents of the bulb and tied it down, and found no evidences of any escape of the fluids The meconium that escaped at first through the incision was mucus tinged with green

I would suggest that a very fine DR DEAN grooved director be used to open the uiethra into the lower part of the bladder, so as to see from before backward, and see whether any point of opening into the bladder exists

DR T F PREWITT presented an

UNUSUAL TUMOR OF THE UTERUS

A few weeks ago a patient, a maiden lady, 47 years of age, came to me with a tumor supposed to be ovarian It extended up above the umbilicus, fluctuated, was evidently a cyst She had recognized its presence five years ago herself, but says that there had been something wrong about the uterus or pelvic organs for sixteen or seventeen years, at least so some physician supposed, and had advised an examshe was 12 or 15 years of age, she menstruated until not distressing news, menstruation ceased for two months, and then returned and continued until five months ago, when it again ceased There has been no indication of menstruation since that time On exam mation I could detect this rounded tumor that, as I have stated, fluctuated It was evidently a cyst On making a vaginal examination, which was a little troublesome because the hymen was intact, I could The ovaries are also intact detect the body of the uterus seemingly, and it gave to me the impression of a rather retroverted uterus from pressure of the tumor upon it I could pass my finger back of the cul-de sac of Douglass and feel the body of the uterus seemingly, passing forward around the cervix, my finger passed up to what seemed to be a sort of projection, a growth which apparently presented a sort of sulcus between the growth and the body of the uterus, as though the tumor was so closely connected with the body of the uterus that they could not be separated, that there was no space between them which could be recognized, still it had by the tumor, there was no fluctuation below, it was on it solid and hard be very much enlarged I was much puzzled to determine the character of the tumor and I saw no reason why it should not be attempted I did not introduce a sound into the uterus, and after wards felt that I had reason to congratulate myself tumor

urethra or otherwise If any had existed I must have She objected to this and said she wanted it out, and that she would rather die than let it remain

Three weeks ago I opened the abdomen, and was one slight incision which I made when dissecting found a smooth round cyst which fluctuated, and which had some solid matter about the walls introuced a Wells' trocar, which let out a dark bloody-like fluid that soon plugged the tube so that it would not flow. I had to enlarge the opening in the abdominal cavity in order to get the tumor out I examined the pedicle, and to my astonishment I found it continuous with the uterus It was evidently a cyst filled with blood At the upper part of what would naturally have been the uterus near the fundus the Fallopian tubes passed out my fingers along and picked up the ovaries, they were all right, and rising above from the fundus of the uterus was this tumor continuous with the uterus The uterus itself did not seem to be very much enlarged, still there was this continuous growth above I could see nothing to do but to remove it, and I did so, strangulating it to a certain extent with an elastic tube—a rubber tube first, and then ligating it, using Tait's ligature There was little bleeding from one of the vessels I found an opening in the lower portion of the cyst-I had opened the cyst by cutmation, which she objected to and no examination ting it across-I could readily have passed a probe She had menstruated from the time that I did not pass a probe and am now sorry that I did I closed it by the extra-peritoneal method last summer, when, upon the receipt of some sudden The patient has done pretty well although there has been some suppuration in the track of the wound, and seemingly a slight intra-mural hæmorrhage removing the dressing on the eighth day considerable bloody fluid escaped from the walls The lower portion of this tumor is undoubtedly uterine was plain to me that it was uterine tissue, yet it was entirely above the Fallopian tubes, which are intact

Here then, was a cyst that under ordinary circumstances we would suppose to be an hæmatometra, vet unique in its character The woman had menstruated regularly for twenty-five years She complained of some pain in the back, it is true, on the day before and the first day of her menstruation, but many women complain of pain during menstruation menstruated usually about three days, and has never had any irregularities in that direction She menstruated until five months ago, yet she certainly had a tumor five years before Hæmatometra are usually the result of an obstruction of the vagina or of the the feel to me as though there was a sort of sulcus cervical canal by some means, either the result of in-Evidently the uterus was closely invested flammatory action or the encroachment of a tumor This was not the case in this patient The uterus did not appear to me to had menstruated regularly without any trouble what-Where then did the blood come from? And ever That it was a if it was an hæmatometra, how did it happen that cyst I was satisfied, but told her there was something the whole cyst was above the Fallopian tubes? Here unusual about it, that it was not an ordinary ovarian was an opening that seemed to extend down into tumor However, she was an your to have it removed, the cavity of the uterus, but the whole expansion of the tumor almost was above the Fallopian tubes There is a thick wall I cut through to get rid of the that I did not I suggested to her an exploratory sue, above it had so changed that it no longer re-The lower portion at least was uterine tislaparotomy, and that if I found out I could not re- sembled uterine tissue, it was not only a thin wall move it there would probably be no great injury above, but there was nothing like uterine tissue

I don't know whether the probe would stances in connection with this very interesting case about it have gone into it from the cervix or not, but I felt is, as the doctor has well stated, his failure to intro that I was fortunate in not having made the attempt, duce through the opening a probe into the uterine for if I had passed a sound into the uterus and could cavity, and we can judge only, therefore, from the have entered the cavity I would almost certainly) have set up a disturbance that would have resulted) in destructive changes, a septic condition, and my patient would have been infinitely worse When we peritoneal indicates their most usual localities From have hæmatometra under ordinary circumstances the appearance of this tumor, from the fact that a we can certainly expect the body of the uterus to be portion of the tumor removed is apparently-and I distended, that certainly was not the case here, the say apparently, because no microscopic section of it body of the uterus is still within the abdomen, and has been made—a continuation of the uterine wall, -the Fallopian tubes and ovaries are still intact whole expansion has taken place in the upper segment of the uterus above these appendages, and has a large blood-vessel On the inner aspect, perhaps taken place while the woman was menstruating regu-This is something very unique in the history of hæmatometra This woman was 47 years of age Hæmatometra much more frequently occurs in young girls, although it has occurred in older women, women 45 and even 60 years of age, but it is very rare in women of that age

In answer to several questions Dr Prewitt said that so far as he knew the uterine cavity was left in-What was removed was simply expanded uterine tissue, where it was cut through it was clearly uterine tissue, but there were no indications of uterine tissue in the upper portion There was no septum between the cavity of the uterus and that The opening was plainly visible, and of the cyst seemed to pass down into the cavity of the uterus He did not close the opening The pedicle was treated by the extraperitoneal method There was not much hæmorrhage He did not know whether the canal leading from the cavity of the uterus up was perfectly developed and supplied with a lining He did not pass a sound, either per vaginam or from above into the pedicle, but the opening passed down in the direction of the uterine cavity In answer to a question by Dr was the question Lutz, as to what was made to constitute the pedicle? In addition, we have a tumor in a woman at the age Was it a portion of the uterine body that was con-

It seemed as if dilatation DR PREWITT replied had taken place in the upper segment of the uterus, and could not expand any larger without involving the lower portion of the uterus larger than normal was simply uterine wall, the upper portion was thin oped by Dr Martin, of Berlin I would like to hear cyst wall simply a continuation of the uterine tissue I cut it } off straight across and closed it up The only explanation that presents itself to my mind is that it the anatomical construction of the tissues involved was a biparte uterus, and one-half only of the cavity or of the uterus to cause him to prefer the extra had become distended with menstrual blood, the peritoneal method Every case of hysterectomy that other had gone on menstruating, and through some comes up ought to be viewed with that point in view, difficulty or other, a distension has taken place in and an endeavor should be made to determine which one side only, one side has become distended, and of the methods is preferable a unilateral hæmatometra has occurred We do at the outstart, that the intra-peritoneal method will have uterine fibroids sometimes breaking down in supersede the extra-peritoneal, just as the intra-perithe central portion, forming a cyst this was a tumor of that character

appearance of the tumor as to its nature. It is a well-known fact that the ordinary division of uterine fibroids into the sub-mucous, the intra-mural and sub The and that the contents of the tumor are coagulated blood, and that the thinner portion is nourished by to the right of where the incision was made to show the contents of the tumor is what I think is a bloodvessel It has all the characteristics of a blood-vessel, and is about the size of the radial artery. It occurs to me that this tumor was a intra-mural fibroid at first, and as it gradually grew, growing in the direction of least resistance, it became a subperitoneal tumor and fibroid, and from what we know of the natural history of fibromata of the uterus, they are liable to undergo almost any kind of degeneration, so that we have in many instances a combination of the fibroid with cystic degeneration of perhaps only a portion of the so-called fibro cystic tumor of the uterus The argument for assuming this to have been a tumor of the uterus, and not a double uterus, 15, 111 the first place, its peculiar position It is one of the rarest things to have a double uterus with one portion situated higher up than the other The ordinary configuration is that they are situated by the side As I understood the description, the broad ligaments, the Fallopian tubes, the ovarian tissue, in fact all those tissues in which ordinary cystic tumors, or in which neoplasmata develop, were perfectly normal Here we have a tumor covered by peritoneum, occur-Why the fluid did not go into the uterus ring above the uterine body, with no adhesions, no kind of connection with any of the adjacent tissues when we ordinarily expect to find fibromata, and tinuous with the upper portion of the cyst wall? more than that, at an age when we expect to find the changes which fibrous tumors undergo to take place Now the same struggle is going on so far as hysterectomy is concerned, the question of whether or not to The uterus was insert a stump of the uterus into the abdominal wall, The lower portion of the tumor or else treat it intra-peritoneally as especially devel-There was no distinct pedicle, it was Dr Prewitt's reasons for treating the pedicle in this case extra-peritoneally—whether he believes it was the safer method, or whether there was anything in I believe, as I stated I don't think toneal method of treating the pedicle of ovarian tu mors has superseded the implantation of the pedicle DR LUIZ One of the most unfortunate circum- into the wall of the abdomen About the time of

a degenerative process. I perfectly agree with those was some other growth than simply the result of the who say that it is impossible to determine the nature of this case from the microscopic appearance To all appearances it seems to me that the tumor is continuous with the uterine wall. I believe, then, that peculiar if it were a double uterus the tumor is a uterine fibroid which has undergone cystic degeneration the intra peritoneal treatment of the pedicle is preferable is a question which is as yet sub judice tendency in abdominal surgery is toward the performance of the ideal operation, to endeavor to treat the pedicles of extracted tumors intra peritoneally, the success of ovariotomy in that respect, and the gradual transition from one method to another will perhaps be followed in the treatment of hysterectomy You will remember that Spencer Wells has had more to do with diverting the treatment of ovarian tumors than any other operator His first method. and in fact that of the most operators was to treat the pedicle of ovarian tumors extra-peritoneally

THE PRESIDENT said that Dr Bond had expressed his idea as to the character of the tumor. He thought it was an intra-mural fibroid with a tendency to be-

-come sub-mucous

DR WALTER COLES I agree with Dr Lutz in all that he has said in regard to this tumor, but there is one other point which suggested itself to me from the imperfect examination which I made, and that is with regard to the character of the contents of the tumor If this were a double uterus, if the upper cavity were a portion of the uterine cavity, that would of course have the ordinary mucous lining of the uterus, and the accumulation of fluid in the tumor would be mixed Is said to have had "lock-jaw," but can swallow now with epithelium and partake of the character of I understood that the tumor con- her pulse 140 menstrual blood specimen does not agree with this, in other words it would be likely to occur, the blood would remain lent muscular contractions perfectly fluid, or in rather a treatly consistency, the tumor were examined this blood-vessel—and not only one, but there are a number of smaller ones also coming up from the wall Took beef tea and milk freely of this tumor, making their way into its disintegrating tissue, whether it be coagulated blood or a portion restless all night in spite of opiates of the tumor In these fibroids it seems to extend as the tumor grows, the wall seems to grow thinner, disintegration takes place in the interior of the tumor going on toward the surface, and as we approach the surface the wall becomes more and more highly ormaking their way toward the interior of this tumor How soft it was at the time it was removed, before it ened I am unable to say The whole appearance of the with no effect

the menopause fibrous tumors are liable to undergo contents of the tumor would lead one to believe it coagulation of menstrual blood in a double uterus or in one side of a double uterus Then, as Dr Lutz has already stated, the situation of the tumor is very

> (Subsequent microscopical examination of the Whether or not the extra- or tumor showed that it was a degenerating fibroid ?

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, November 16, 1887 THE PRESIDENT, JOS TABER JOHNSON, M D, IN THE CHAIR

DR P. I MURPHY reported a case of PUERPERAL TETANUS

Mrs Annie B, white, at 24 years, nativity Germany, was admitted to Columbia Hospital on the evening of August o, 1886

Her husband stated that she was delivered instrumentally of her first child three weeks ago by Drs Sellhausen and Sowers She did well for the first nine days On the ninth and tenth days she sat up and on the latter day began biting her tongue, and "spasms" soon followed The spasms had been occurring frequently since, and accompanied by high temperature and profuse perspiration The day before admission she "broke out" all over her body

When admitted her temperature was 103 6°, and The eruption was thought to be due tained menstrual blood, but an examination of the to excessive heat Bowels very constipated Gave calomel grs v, triturated with sugar Patient was shows that there is a great deal of coagulated blood restless and delirious all night, having frequent spasthat has undergone partial disorganization, that it is modic attacks with episthotonos Temperature 104° in layers, that it is organized in layers, that it is ad- and pulse 140 all night. Toward morning, under herent to the wall of the cyst. Now if this were a the influence of hypodermic injections of morphia, double uterus, I don't think anything of that kind she slept some, but would awake suddenly with vio-

August 10, 5 A M — Temp 104 2, pulse 125 She something like molasses, at least it would be mixed continued about the same all day Enemata were up with more or less epithelial cells, which would given several times, but were immediately ejected render the diagnosis certain if any of the contents of Skin bathed in profuse perspiration all day, notwith-Then the presence of standing frequent spongings Had frequent attacks of episthotonos, and was continually dribbling urine

Aug 10, 7 P M — Temp 105 6°, pulse 132

Aug 11, 6 AM — Temp 1048°, pulse 124 Emplast canthar applied to back of neck and an ice Emcap kept on head all day Took nourishment readily but was delirious at times At 2 15 PM temperature was 1058°, pulse 142, at 3 PM temperature gamzed until at last we meet with blood-vessels It was 106°, pulse 142, at 6 PM temperature dropped seems in this specimen as if these blood-vessels are to 105 2°, and pulse was full and strong Was given 15 grains antipyrin, and heart's action rapidly weak-Ordered tinct digitalis to drops every 3 was subjected to the action of the alcohol of course hours Enemata again tried and comp cath pills,

At or M, pulse being stronger and temperature remaining at 105°, she was given 15 grains more of antipyrin

Aug 12, 12 15 A M — Temp still 105°, and patient

delirious, gave third dose of antipyrin

7 AM—Has not slept at all since the 10th inst

Gave cath pills again

9 A M — Temp 105 2°, pulse 140, and feeble Antipyrin having no perceptible effect except to weaken heart's action, was discontinued, and dose of digitalis Patient scems brighter and is more quiet Another blister to back of neck

3 PM—Has slept two hours and bowels have moved three times, but her condition is much worse Pulse at wrist almost imperceptible

5 PM —Temperature suddenly ran up to 107°,

and pulse too feeble to be counted

Patient is unconscious 7 PM — Temp 108 4° and her breathing stertorous Usual restorative measures were employed, but patient died quietly from butter in the market? at 8 30 P M

The convulsions gradually lessened in frequency smell and intensity from the time of her admission until the evening of the 11th inst None were noticed

after that

Dr Sellhausen called at the hospital August 19th and stated that he attended the woman during her confinement, and that she was delivered by forceps The perineum was ruptured, sutured, and healed by She was seized with convulsions on first intention the thirteenth day after delivery Her extremities became rigid and her jaws locked He gave her one-fourth grain morphia and 20 grs chloral hydrate every two hours

I have contented myself with the simple recital of this important case, the first I have seen after sixteen years experience in a lying-in asylum To those interested in the subject, a perusal of Dr Garrigues' article in the American Journal of Obstetrics, Vol xv, October, 1882, will not be without profit, also the case reported by Dr Boarman, of this city, and read before this Society May 18, 1887, with the dis-

cussion following

Was there hæmorrhage or lacer-DR BOARMAN ation of the cervix? What was her temperament?

Was she subject to spasms or hysteria?

DR MURPHY only knew what Dr Sellhausen had When she was brought to the hospital she was suffering from stupor alternating with delirium There were jerkings about the face and neck, the opisthotonos would come on and her head would approach her heels, and finally she would give a bolt and almost fall out of bed She was plethoric

Tetanus occurring after labor at Dr Boarman full term is very rare, but that occurring after abor-Callabin did not have a case tion is more common in 46,089 labors In 1849 P Anbinaus reported three cases 'Merriam collected 10,190 "cases of difficult labor with 106 deaths, and only one died of tetanus" Curling thinks it is more likely to follow lesions of the cerebro-spinal than the sympathetic in the cases he examined In only two were the of Chronic Empyema 4 Recurrence of Malignant labors perfect v normal

Dr Garnett Puerperal tetanus can hardly be caused by lacerations of the cervix, but must be due to some constitutional peculiarity. In forty years of practice he has never seen a case after a labor at full He has seen one follow abortion

DR THOMAS TAYLOR then presented some

PACTS IN RELATION TO EMACIATION

(See p 265)

DR Busey asked Dr Taylor if there were any distinct characteristics by which ordinary people could distinguish oleomargarine from butter?

Dr Taylor It is very easily distinguished The crystals of oleomargarine may be detected with the naked eye by placing a small portion between two slips of glass and holding it up to the light, the translucent particles being crystals of fat, butter under like conditions presents an even cloud

Can anyone tell oleomargarine Dr Friedrich

It can be told by the taste and Dr Taylor Oleomargarine has no odor and a lack of taste, while butter has a pleasant odor and taste

The subject of this paper, viz Dr Schaeffer the discrimination between different kinds of fat, presents two aspects one in a biological light, as bearing on the possibility of distinguishing between different species of mammals by a supposed distinctive structure of the tissues in each, the other in a sanitary light, as it bears on the possibility of detecting fraudulert adulterations of butter as an article of food

While I have not examined so extensive a list of fats as those mentioned in the paper, I have arrived at the conclusion that the microscope is not a safe guide, with our present knowledge, when we endeavor to distinguish animal fats by their crystalline structure alone The gentleman's statement, that all butter showing small crystals visible to the eye on pressing some of the sample between two glass strips must be rejected as spurious, is an erroneous one, as crystals of salt are frequently found in good "firkin" or "tub" butter Is it not also illogical to expect to find a similarity between the solid fat of the sheep, hog, etc , and the only product of the cow's lacteal gland—a gland hypertrophied by domestication and artificial selection? The use of solid fats as a remedy in tuberculosis is contraindicated by the proverbial distaste of patients for such food

FRENCH SURGICAL CONGRESS —The third session of the French Surgical Congress will be held in Paris, from March 12th to the 17th, in the large amphitheatre of the Administration de l'Assistance Pub lique, 3 Avenue Victoria Professor Verneuil will The following questions are down for dis-I The Treatment of Gunshot Wounds of preside 2 The Value of Radical Treatment of cussion Herma as regards Permanent Cure 3 Treatment Growths after Operation its Causes and Prevention

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Antiseptic Treatment of Boils—Enlargement of the Bi easts in Tuberculous Subjects—Angina Pectoris of Syphilitic Origin—Strophanthus

Professor Verneuil, well known as the champion of conservative surgery, lately made a communication to the Academy of Medicine on the antiseptic treatment of boils and carbuncles The author observed that the treatment of carbuncle has greatly varied within the last forty years, but has gradually become less surgical, without on this account being After having tried in common with other surgeons the old method of free incisions and punctures the result of which was anything but encouraging, Professor Verneuil resorted to the thermocautery, followed by carbolic acid dressings But as he now obtains the same results with the carbolic acid spray alone composed of a 2 per cent solution which he employs for two hours daily in two, three, or four sittings at the convenience of the patients. and with a powerful instrument. This treatment is adapted to all the forms, to all the phases, and to all the stages of the disease At the outset the carbuncle has the character of being aborted Later on, disease progresses, when perforation and mortification of the dermis have commenced and when suppuration and the elimination of the cores of the abscess are proceeding, this treatment limits the sphacelus, favors the separation of the sloughs, carries off mechanically the pus, disinfects and deterges the wound, and lowers the body temperature which is accompanied by the cessation of the general symptoms When the subject is not cachectic, the granular memloss of substance and the suppleness of the surrounding integuments would permit Dr Perrin, of Valde Grâce, stated that he employed another method with success, which consists in prolonged baths in hot water, and the application of a cold starch poultice during the night A discussion followed in which several members took part Dr Le Roy de Méricourt, an old navy surgeon, did not believe in the microbian nature of boils and carbuncles As to the treatment, he states, that if it be true that the carbolic acid acts to practice an injection into the substance of the carbuncle, as is done with the tincture of iodine in malig Should the patients feel relieved and although there was a manifest tendency towards the oughly that they seldom or never return To the objections that were made against

no right to criticise it Moreover, although he has now adopted this method as a general rule, he did not wish it to be inferred that this was done to the exclusion of operative measures in suitable cases but that he employs the thermo-cautery in preference to

Tuberculous subjects sometimes present enlargement of the breasts, which, in certain cases, assume an inflammatory character Leudet, of Rouen, brought to the notice of the Congress of Grenoble, in 1885, several cases belonging to this first category In his thesis for the doctorate, entitled "Contribution to the Study of the Hypertrophy of the Mammary Gland in Pulmonary Tuberculosis," Dr V Allot states that, from his personal observations, he found that the development of the breasts takes place in an indolent and progressive manner mary glands never attain a very great size, but the emaciation of the body contrasts with this development of the breasts The skin presents its normal When a breast thus hypertrophied is excharacter amined with the hand, one feels the sensation of a hard mass, including the whole gland, without any adhesions to the skin or to the deep parts, and no puffiness of the subcutaneous cellular tissue is ob-This affection never terminates by suppuration, the regression of the breasts is never complete, and the nodosities in them always persist anatomical point of view, remarks the author, the should this result not have been attained, and the malady is constituted by an abnormal development of the fibrous tissue forming around the ducts and the lobules of the gland thick zones, diffused, and which tend to atrophy the glandular elements absence of abscesses of tubercles, of glandular enlargements remove the idea of mammary tuberculosis The author concludes that this hypertrohpy of the breasts is in reality caused by a chronic interstitial

In the Annales de Dermatologie et de Syphiligraphie, brane once deterged has generally a good aspect, and Dr Hallopeau contributes an article on angina peccicatrization proceeds as quickly as the extent of the toris of syphilitic origin Syphilis, according to the author, may give rise in its secondary and tertiary stages, to attacks of angina pectoris, and these attacks may present the classical type of this affection At times the attacks are complicated with other troubles of innervation connected with a reflex excitation of the vaso-constrictor or of the vaso-dilator nerves, thus provoking abnormal sensations of cold or heat in one half of the body with shivering and hyperhidrosis, and may give use to paresis by ischæmia of the motor centres These fits are attached to as an antiseptic, he thinks that it would be preferable the development of specific neoplasms on the course of the cardiac plexus or in its immediate neighborhood, and they may be modified in their character under the evolution of the lesions, of their arrangethe disease amends by the carbolic acid spray, he ment in the points primarily affected and of their believes it to be due to the cold water and not to the extension to other branches of the sympathetic nerve acid Several other members then gave the result of These attacks the author remarked, may be cured in their experience, all adhering more or less to the old a few days under the influence of the mercurial medmethod, that is to the medical and surgical treatment, lication or of the iodide of potassium, and so thor-

At a recent meeting of the Sociéte de Thérapeuthe use of the carbolic acid spray, Professor Verneuil tique, a discussion took place on the therapeutic acretorted that those who had not tried his method had tion of strophanthus According to the experience of Dr Constantin Paul and other members of the Society, strophanthus is less a cardiac medicament than a feeble diuretic, but of persistent effect

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORPESPONDINT)

New York County Medical Association—Dr Alonzo Clark-The Medical Profession as a Whole, and Physicians as Individual Members —- The Care of the Pauper Insane

The last meeting of the New York County Medical Association was occupied by the addresses of the retiring and incoming Presidents, both of which were able and interesting Dr John Shrady, whose term of office then came to a close, reviewed the work of the Association, and expressed the conviction that all the members could truthfully say that the year had added somewhat to their mental stock and directed their thoughts into newer channels Having referred to the past year as being, in a general way, not very notable for brilliant discovery, although much good work had been done in the line of corroboration of that which is valuable, he characterized the Ninth International Medical Congress as a success, and averred that there were but few leaders capable of directing intelligent thinkers by the thousand, maintaining that no one man or body of men can lay claim to indispensability that the phantasm of a possible medical centre for so large a territory as the United States had been dispelled forever, and pointed out that there had been many surprises, chiefly in the direction of the newer men, who snatched at the prizes abandoned by the older favorites

Dr Shrady attributed the success of the Associa tion to the absence of medical politics, the encouragement given to latent talent, the elimination of dogmatism, the suppression of offensive individualism, and the care taken to make the contributions as exhaustive as possible The acrimony of debate, he said, had gone out with the bickerings of the politician and the vaporings of the pseudo-reformer

He then alluded, in feeling terms, to the death of Dr Alonzo Clark, one of the greatest of New York teachers, who, he claimed, was just to all, supercil-10us to none, safe almost to plodding, and free from dogmatism, and who, as an honest toiler, with no meretricious aids, always gave what was best of his Avowing that loval nature to science and to truth there was no courtesy in science, he disclaimed all hero-worship, and earned, along with the best of his ideas—who, from an innate judiciousness, which they colleagues, the laurels of the ideal physician

graceful reference to the verdict of the Scottish clans follow the dictates of common sense, and they there contending for precedence at a feast MacGregor, there is the head of the table "

ful and carefully prepared essay devoted to reflect the moral support and encouragement they efford, The address of the President-elect was a thought-

tions concerning the medical profession as a whole and physicians as individual members thereof, and the following extracts may serve to afford some idea of its character The exact status which the profession holds in the complicated arrangement of hu man society is in some respects peculiar. The interests with which it deals are obviously second to none in importance The most natural instinct of man is to preserve his health, and much of his time and attention, in one way or another, is expended in serving this object, and, notwithstanding his depraved inclinations and the tendency to excesses, it lies as a substratum in his moral nature, even though it may be dormant

Although our relations with the community are close, and affect those matters which lead all others in importance, so far as this life is concerned, yet it is in a single line of duty, our points of contact with the world at large are few We are to a certain extent a segregated class, and virtually constitute a caste, while most of the other higher pursuits in life bring their members more or less into the range of public notice, and the subjects which they agitate mingle to a considerable extent with the topics of public A certain portion of the community, as interest individuals, certainly do manifest a desire to know something of medicine, and those with this inclination, whose temperaments are by nature tinctured with the element of vanity, occasionally pique themselves upon their scientific acquisitions With a person of this description for the physician to acquit himself judiciously, serving the best interests of the patient and at the same time having the difficulties presented by a garrulous subject to deal with, is often a problem not easy of solution

With many the vague and popular notions handed down from antiquity still hold their sway, with their admixture of mystery, superstition and deceit The forms become somewhat modified under the progress of education and advance generally, but they still retain the root which belonged to their original type It is only a change of dress suited to the fashion of Higher in the scale of enlightenment the day comes he who does endeavor to mould his actions and discover his best interests by the judicious exercise of the light that is in him, but it is too fre quently the case that one whose experience and Judgment would enable him to successfully conduct a difficult mercantile project, or another who could apply the highest order of reasoning to a profound principle of law, cannot hold out against the assaults of promise, plausibility and pretence in seeking There are others, again-and medical resources they do not belong to any particular station in life, nor do they always have the advantages of education or those associations which tend to enlarge the are able to exercise in all directions, in medicine as Dr Shrady introduced his successor in office by a in other matters, think that the wisest course is to "Where sits fore apply to those who, by education, training and experience are supposed to be qualified to attend to their medical needs Were it not for these, who by

do much to sustain him, the path of the physician

would indeed be gloomy

That the avenues to knowledge are open for all goes without saying, but a successful search for the choicest fruits is only accomplished upon certain It involves an intensity of interest and fixedness of purpose which falls little short of a devotion, and it calls for an amount of industry and self-denial such as only few can practice He who cannot furnish these qualifications will reap as his harvest little but the results of a blasted or spurious There is a vast difference between a germination knowledge that is ample, well ordered, and in a condition ready to be applied with effect to a definite, useful purpose, and that which is the offspring of a few smattering, disconnected notions, of fancy, and of false intuition

The arduous and responsible duties of a medical man in active practice call for some diversion from their wearing effects There must be some resource by which the mind can occasionally be lifted from the weight which forces it in the embrace of an anxious contemplation, but it does not necessarily follow that the relief is to be sought for solely in light and frivolous entertainment. There are other channels which, in part at least, afford a means of obsome study of a scientific or other character will often fulfil the demands of nature in this need not claim that the practice of medicine is excepevercised or strained to a higher degree that would occur in the application of the mental faculties over a considerable time—provided the capacity was proportioned to the magnitude of the daily effort required, and the application not begun at too early an age-would probably be small, if it was purely of an intellectual character, as is evidenced by the longevity and retention of the mental powers of those who devote their attention to philosophy, metaphysics, and the sciences generally It would hardly be appropriate to this occasion to which exemplify the physician's anxieties, we know well what they are, and we all feel their weight

It is perhaps not out of place to say a word condisease, this has a partial application We might doned have pursuits and sympathies in common

worthy physician, you have the stamp of nobility, and the hand of fellowship is extended to you, while your efforts here will tend to round out and complete the professional character to its proper symmetrical proportions

At a recent meeting of the Academy of Medicine Dr Samuel Sexton introduced a resolution (which was unanimously adopted), endorsing the bill prepared by the State Charities Aid Association, in regard to the care of the pauper insane in State hospitals, and recommending its enactment by the Leg-

In seconding the resolution, Dr C R Agnew said that for thirty years he had been interested, with others, in the amelioration of the condition of the pauper insane in the State of New York, and that the first result of the agitation of this subject had been the establishment, by the State, of the admirable Willard Asylum Later those at Binghamton and Poughkeepsie had been started This opening of these institutions had withdrawn a considerable portion of the pauper insane from the county poorhouses, but now an effort was being made to estab-

The chief reasons alleged for this movement were the saving, to a considerable extent, of the cost of taining the required relief, and even the pursuit of transportation of insane patients, and because it was claimed that the cost of maintenance in the State I do | hospitals was unnecessarily great One of the counties declared its willingness to undertake the care of tional in presenting more troubles and vexations its insane at a cost not to exceed 97 cents per head than is experienced in some other pursuits, but it per week, and another for \$1 19 At the Willard will, I think, be conceded that there is no other in Asylum, where the number of inmates is now nearly which the emotional faculties are more frequently two thousand, the expenses could not be reduced The below \$2 25 per head per week, but this included amount of permanent damage to the nervous system the best scientific care by expert physicians and specially trained nurses, the amusement and intellectual training of the patients, and their employment in the work-shop and on the farm connected with the institution The counties, however, did not propose to give the same character of care to their pauper insane as that given by the State hospitals, as this was impossible of attainment for any county at a weekly cost per capita of \$1 50, the charge to which the counties were subject by the provisions of the State Charities Aid Association bill The expense enter into any extended relation of the situations of new or improved county buildings, and of a larger number and higher grade of attendants-to say nothing of maintenance and medical treatment—nould They vary, of course, with the exigencies of the case, impose a heavier burden on the tax payer of the but it may be safely asserted that there is no single county than the additional increase of his State tax professional act performed of which they constitute required to perfect the system already established by the State

It was a fact, also-Dr Agnew continued-that cerning the claims of medical societies upon its some of the counties had tried the experiment of members, and in view of what has been alluded to having their own insane asylums, and unsuccessfully in the necessity of the physician to have some diver- Thus, Rockland county had erected one at an exsion of his attention from the daily conflict with penditure of \$20,000, and it had now been aban-If the pauper insane were cared for by the say that here is the home circle of our professional counties they would be under the charge of the subrotherhood, here you can meet with those who pervisors and superintendents of the poor, and these Whether men, besides knowing nothing of the proper care of you are fortunate enough to be distinguished or not, the insane, were altogether too close to the tax payif you bring those attributes which belong to the ers This class of cases could, in fact, be properly

taken care of only in an institution where there was basis of medication, and often of itself sufficient to a board of managers which was directly responsible cure as well as prevent disease, the regulation of the to the State, and where everything was done in the full blaze of public scrutiny, and in the State hos- light, heat, clothing, rest, exercise, mental and moral pitals of New York he believed that the most en- conditions, etc, according to circumstances, being lightened modern treatment of the insane was car- necessary also in unison with this system of counter ried out in as thorough a manner as was at present action or anti-pathy, as right living is essential for the attainable

MEDICAL SCIENCE

Dear Sir —If physicians would have the following or something similar published in the newspapers and popular press everywhere, they would greatly help to enlighten the people and diminish quackery of every Lind

There appears to be a great misapprehension existing respecting the character and scope of medical science It does not consist of a single pathy or ism, or of many shreds of pathics and isms, but of all knowledge, all truth pertaining to life, health, disease, deformity, injury or abnormity of every kind, and their treatment, in their most extended relations Hence, pathies and isms do not represent and have no place therein, while the real knowledge and truth included in every phase of thought, pathy, ism, or otherwise, belong to and are comprised in the general science of medicine, which is thus of universal compass The application of the term "allopathy" to legitimate medicine is a misnomer and savors of the case under treatment. But scientific physicians quackery, while that of "allopathist" applied to the regular physician, which he repudiates, is libellous and actionable as expressive of an untruth, a stigma The only pathy at all applicable to and reproach the science of medicine is anti-pathy, or antagonism to all disease, but even this is too limited and misleading as to its nature and extent, as it only includes the mere prevention and treatment of disease, and omits all the collateral branches of biological, and many of surgical science This law of antagonism and principle of counter action applies to curative medicine the same as to everything else, as it is uniform and universal, and does not admit of any exceptions, much less such a sophistical dogma as "similia similibus curantur," or like cures like of The dictum that to cure one disease homœopathy it is necessary to produce another of the same kind or similar to the one existing, and then that this like stronger and conquering disease gets well of itself, which it must do if so as asserted, is sheer assump-The victim of one disease does tion and nonsense not want, and should not be afflicted with another disease of any kind whatsoever, whether the same (isopathic), similar (homeopathic), or dissimilar (allopathic), but wants to get well in the most direct way as easily and speedily as possible, which it is the object of scientific medicine and physicians to accomplish by all the most appropriate physical, mental and moral means which can be favorably brought to bear upon the case by this law of antagonism with counteracting and antipathic agencies, of symptoms as given in the article referred to which mere drugs of themselves are often of minor importance, though generally useful and frequently indispensable. Yet, in general, alimentation is the within the first ten days or, dropping to 102°-103°,

diet, with the other hygienic measures of pure air, restoration as well as preservation of health fore, for the removal as well as prevention of disease, with abnormities of all kinds, this law of antagonism prevails, as anti-pathy inculcates and anti-pathists adopt such measures as are counteractive to disease as well as every other derangement, whether of a physical, mental or moral nature, that will restore the equilibrium of health, consisting of anything and everything material, dynamical or spiritual, appro priate therefor, the precise character and combina tion of which depend upon the peculiarities of the

With regard to drugs alone, they are administered in every form, proportion, variety and way crude or refined, single or miltiple, separate or combined, small or large doses, each have their special appli cation and are employed as necessary, the judgment of the physician deciding the particular kind, form, quantity, simple or complex nature and condition, whether organic or inorganic, mineral, vegetal or animal, solid, liquid or gaseous, and otherwise, singly or combined, specifically adapted antipathically to discard all exclusive dogmas, pathies and isms, as being too narrow and sometimes fallacious, though they counteract disease as well as abnormity of all other kinds by this sound, common-sense law of an tagonism or anti-pathy, which may not always save life, just as carbonic acid and water against fire may not always save property, yet they are specific there for nevertheless, assured that it is the only rational method and true system to cure as well as prevent disease, that the science of medicine is one and uni versal in its range and application, while ever pro gressive, new discoveries, new truths, new remedies and other instrumentalities being constantly added in its onward course towards perfection, despite all dogmas, pathies or isms Thus, in the estimation of all true physicians,

"No pent-up dogma restricts our powers, The boundless universe is ours'

SYMPTOMATOLOGY OF TYPHOID FEVER

Dear Su -In The Journal of January 28 your correspondent in Cincinnati describes the typhoid fever prevailing in that section, during the last sum mer, as differing in symptomatology from the fever The general run of the described in text-books disease as it occurred here during the spring, sum mer and autumn of 1887 presented about the same remain at this for one or two weeks Headache and backache were the most prominent symptoms complained of by the patients, many tracing the latter directly to some exertion, and asking for relief from a "lame back" These symptoms were always ac autumn, bronchitis was a common complication, ammonium salicylate hypostatic congestion of the lungs, however, occurred in only the most severe cases inal symptoms we had pain extending from the right at 7 P M moid flexure, with, in some cases, diffuse tenderness on pressure throughout the entire abdomen Con-Intestinal hæmorpanites but seldom very marked rhages were few, but severe be definitely established Hæmorrhages of the nose were not often observed

As to treatment of the cases, quinine, natr salicyl, and antipyrin did not act satisfactorily in my hands, for, if given in doses large enough to depress the temperature, it would remain so only for a short time, returning to its original height in the course of ten or twelve hours, notwithstanding the constant administration of the antipyretic

The remedy par excellence proved to be the ammonium salicyl, to which my attention was attracted in typhoid and septic fevers, in the Transactions of the State Medical Society of Wisconsin, by Dr J R It invariably reduced the Barnett, of Neenah, Wis temperature to 99°-100°, keeping it there during the entire course of the disease, diminishing the rate and force of the pulse and causing, in a majority of cases, profuse diaphoresis When given early, within the first few days of manifestation of the disease, it In cases not seen until the end of the first or about the barn beginning of the second week, such drugs as were above normal after the first decline indicated were added to the am salicyl mixture ten or twelve days at a time to counteract the dein the few cases that were accompanied by diarrhoea Bromide of potassium was always used in conjunction to combat the severe headache, and when the patients complained of pain and weight in the back part of the head and neck the fluid extract of ergot The turpentine and opium mixture advised by Dr N S Davis, without the opium, was given in all cases presenting a dry state of the tongue and sordes on the teeth

I am unable to give an explanation of the action at the bedside, that it has proved itself to be a very efficient remedy in the treatment of this diseaseshall we call it typhoid fever? Some undoubted

A remarkable circumstance I omitted to mention is that the skin was always hot and dry, except in the few cases of genuine fever above referred to, while our text-books claim it to be always moist and clam I did not keep an exact memorandum of any companied by a general feeling of lassitude During | cases, but a few are well enough remembered to cite prevalence of the cold weather, both in spring and as giving an illustration of the prompt action of the

Fr G, æt 21, German, laborer Began to admin-For abdom-lister medicines to him on the ninth day of the fever Had a few days previous to this given diiliac fossa, along the course of the colon, to the sig- rections about opening the bowels, and general instructions regarding the treatment, to his father, a German minister, who is a very devout disciple of stipation was the rule, diarrhoea the exception, tym-electro-homoeopathy At the time mentioned the young man presented a woe-begone appearance, As no post-mortems being well plastered with white, red and green elecwere held, ulceration of Peyer's patches could not tricity à l'Electro homeopathie to relieve him of a distracting headache His face was flushed, skin hot and dry, tongue covered with white fur, breathing accelerated, pulse hard and full, beating 120 per minute, temperature 105 2° There was considerable tenderness along the course of the colon, bowels had been moved with mag sulph, the stools were watery, containing flakes of a yellow color I placed him at once on a mixture containing am salicyl gr viii, tr aconiti gtt i, pot brom gr vi, ext ergot fld gtt in to each dose, with directions to administer the medicine every two hours during the night Next by reading an account of the usefulness of this salt | day at 10 AM his temperature was 97 8°, his pulse soft and full, 96 per minute, he was perspiring freely and entirely free from headache His bowels had not moved, and I ordered one tablespoonful of castor-oil to be given and repeated in three hours in case his bowels did not act. The dose of the mixture given above was reduced one-half and, as the tongue evinced a tendency to become dry, turpentine in 8-drop doses every four hours was prescribed would generally break up an attack, the patient being | At my next visit, two days later, the patient was out able to be up and about the house in two or three of bed, and one week after this he did the chores His temperature never rose to

The other case occurred in February, 1887, before Tincture of digitalis, when the pulse was weak, was I had any knowledge of the value of the am salicyfrequently given in 5-drop doses every two hours for late as an agent in the treatment of these fevers This was a case of more than ordinary severity, one pressing action of the salicylate Tr opin was added the books assign as usually terminating fatally, for the temperature ranged between 103 5° in the morn-

ing to 105 5° in the evening for about three weeks C L, æt 24, nat Swede The entire family, consisting of eight persons, went through a course of the fever This patient was the last one to be attacked and proved the most severe The abdominal and head symptoms were about the same as those described in the previous case, in the beginning of the fever, the stools and urine passing involuntarily about the third week, while an active delinium that set in during the of this drug, but can say from experience gathered latter part of the first week continued night and day for three weeks The pulse was 120 during the day, running up as high as 140 during the night, while the temperature ranged between 103 5° and 105 5° for the cases of typhoid fever occurred during the time, but same length of time Quinine, salicyl of soda, antithe general appearance of the disease was as de-pyrin (in horse doses, as the consulting surgeon expressed it), accompanied by moderate and cold effusions, were each successively used, without ever reducing the temperature for more than 1° or 1 5° for longer than one to two hours Every morning I would drive out expecting to find my patient dead, only to hear that he had passed a very bad night Often I watched by his bedside all night not expecting him to live until morning

I saw Dr Barnett's paper after this patient had been under my care about three weeks, and procured some am salicylate, which I began to administer in 15-grain doses every six hours, but not being satisfied with its action, the mode of administration was changed to 8 grains every two hours Within eight hours the temperature began to fall, and although there was a temporary rise every evening, it reached normal at the end of the sixth day He made a slow and tedious recovery, and it was fully eight months before he returned to work During the course of the disease such remedies were administered at different times as the symptoms called for I found the various formulæ of my honored teacher, Dr N S Davis, as given in his lectures, most excellent to combat the delirium, later on the involuntary discharges these men do not hesitate to state publicly that from the rectum and bladder and the dried and furred state of the tongue

As your correspondent referred to at the beginning of this article, I also ask the question What is the nature of this affection? He gives as a possible solution a contaminated water-supply, the streets having been torn up, and the water being below its usual level in the river, but here none of these causes can be found, for the fever occurred alike in city and country, visiting the settler in his log cabin in the midst of the pine forest, the farmer in the well cleared country, and the city dweller in the centre as well as in the outskirts of the city The supply of drinkingwater was derived at different places from the clear springs, running brooks, wells and the city hydrants, while there seemed to be no special influence at work, either as to the duration or severity of the disease The rate of mortality at one time was quite large, rather more than the average percentage

D SAUERHERING, M D

Wausau, Wis, Feb 14, 1888

UNETHICAL USE OF PHYSICIANS' NAMES

Dear Sir —I have a little grievance to bring to your attention, and to that of the profession at large

In October last, there came to Charleston, Messrs Bernhardt and Matthez, "scientific opticians" from Immediately upon their arrival here they visited all of the prominent physicians, explained that they were opticians—not oculists, nor did they interfere in any way with the oculist-and asked these physicians to give them their names in recommendation of their (the opticians') work, in order that they might publish them Strange as it may seem, many of our most prominent physicians readily signed their names without knowing anything more of them than that they had good names of other men

Before they could publish these names I succeeded in having a special meeting of the County Medical Society called, and stated my case I said "I am

a specialist in diseases of the eye and ear, a member of the American Medical Association and of your Society, I observe the rules and abide by the Code of Ethics, yet you have given your names in recom mendation to men entirely unknown to you, who are not physicians, who say they do not interfere in any way with the oculist, but whose actions and further admissions belie this, for they test the eyes and pre scribe glasses for all who may come The prescrib ing of glasses is known by many well-informed physicians to be a large factor in the practice of the oculist and one that requires the most careful atten tion, and yet these men are bold enough to say they do not interfere with the practice of the oculist I consider that you have done me an injustice, and that when your names appear in the daily press recommending these men that my practice will be materially damaged, and my patients inclined to lose confidence in my ability "

Upon this statement the members of the Society present unanimously consented to withdraw their names, and so they were not used Knapp, Agnew and Chisolm, not to speak of the lesser lights, know but little about prescribing glasses, and they tell persons who may have been treated by any of the above mentioned, that their eyes have been murdered, etc Their charges for glasses are most exorbitant, ranging as high as \$50 and perhaps more One poor woman who consulted them after wards came to me Upon examination it was found that she had cataract in both eyes, and their com bined vision was control of course a glass would be practically useless. They advised glasses that would make her see and would cost fifty dollars, but if she wished her eyes put out to have them operated upon

Now, my cause of complaint is as follows course I cannot prevent their selling glasses, nor can I regulate their charges, but I do think it unkind and not strictly according to the Code of Ethics for physicians standing high in the profession, members of the American Medical Association, and Professors in regular colleges, to give their names for publica tion, thereby misleading the public and injuring the practice of professional brothers who are trying con scientiously to stem the rapid current I enclose one of their advertisements which appears several times a week in each of the daily papers names therein are sufficient to bring these people Very truly yours, practice

CHARLES W KOLLOCK, M D Charleston, S. C., Feb. 16, 1888

CONGENITAL PHIMOSIS

Dear Sin -I find in The Journal of November 19, 1887, an article on "Congenital Phimosis," read before the Section on Diseases of Children at the thirty-eighth annual meeting of the Association, by Professor Wm S Stewart, of Philadelphia, in which he clearly sets forth the reflex manifestations result ing from this abnormal condition, as every careful surgeon of experience has met them, and as have as "I am often been overlooked by the careless diagnostician,

of over-confident and anxious parents To overcome the difficulty he advocates dilatation instead be gladly received by the profession, and with delight by parents having children so afflicted

But how a four bladed instrument, of sufficient strength to accomplish the dilatation, can be thrust into an opening not larger than a pin's head, and dilate the parts without pain or blood, appears to me to be beyond the comprehension of the average surgeon, and an opening no larger than stated is Dr Stewart, however, very prudently often found cautions in using his instrument that it requires care not to get the blades into the urethral meatus, and also not to dilate too rapidly lest we tear the tissues and cause pain and bleeding Consequently it will be necessary to dilate not only once or twice, but often, unless the tissues are torn, to overcome the difficulty, thus rendering the operation many times more painful and tedious than circumcision properly I admit that circumcision as generally performed, is bloody, painful and tedious But when properly performed it is very simple, comparatively bloodless, and attended with very little pain the ordinary method of operating it is necessary to stitch the mucous membrane to the skin after the removal of the redundant prepuce But when properly performed the necessity for this part of the operation is avoided. All that is necessary, is to draw the prepuce well forward and clasp it pretty firmly between the blades of an ordinary dressing forceps in front of the glands, then cut away all in front of the forceps either with scalpel or scissors, preferably the latter, remove the forceps and let the skin retract, then clip out of the mucous membrane over the glands a V-shaped piece up as far as the Apply antiseptic dressing and leave retracted skin the case to nature, and it will give no further trouble, unless there be some inflammatory complication But we are in no more danger from this complication than we are by dilatation, and from any view of the case circumcision is certainly preferable

REMOVAL OF HYPERTROPHIED PHARYN-GEAL TONSIL

Dear Sir -I have just seen an article in the JOURNAL of January 28, by Dr H Gradle, of Chicago, on "Hypertrophy of the Pharyngeal Tonsil," in which he describes various instruments for the removal of such growths He makes no mention, however, nor do I see it mentioned in any work that I have consulted, of a simple device that has served me in several instances with much efficiency of one of Sims' sharp uterine curettes, the stem havpalate retractor, which I also devised (See N Y

with the result of failure in treatment, leaving the posterior pharyngeal wall can be curetted away, or any little patient to suffer and disappoint the expectations small growth removed from the posterior nasal or naso pharyngeal space with ease, Jarvis' curved snare being used for the larger growths The uvula retractor of circumcision Any means by which the abnormal referred to above has proved of especial efficiency in condition can be removed successfully without a all such cases and particularly when very large postebloody operation, and comparatively painlessly, will rior polipi are present, and where under any circumstances the use of the tape and clamp method would be objectionable, if not altogether impossible, but with the palate retractor the parts are easily pulled forward and held so while both hands of the operator remain free to use the mirror and snare or cautery wire

ASSOCIATION ITEMS.

ARRANGEMENTS FOR THE ANNUAL MEET-ING, MAY, 1888

Members of the Association will be pleased to learn that the organization of the Committee of Arrangements for the entertainment of the American Medical Association in Cincinnati in May, has been completed, and that long strides have been taken towards securing for the Congress scientific work of high order and social features that will be at least Dr W W Dawson, the Chairman of acceptable the Committee, has associated with himself a number of representative medical men to aid him in the work of the Committee To facilitate this work the following Sub-committees and Chairmen have been appointed

•		
	Sub committee	Chairman
1	Section-Work,	J T Whittaker
2	Halls and Decoration,	B Stanton
	Entertainments,	N P Dandridge
4.	Exhibits,	J C Culbertson
	Programme,	1 Ransohoff
6	Reception,	J T Whittaker
7	Finance,	S C Avres
8	Registration,	Jas M French
9	Printing and Invitations,	J C Culbertson.
10	Transportation and Hotel,	Geo Purviance

Music Hall has been secured for the second week Under its vast roof the various Sections of the Association can be easily accommodated seating capacity of the rooms for Section-Work varies from about 70 to 300 Their acoustic properties approach perfection

By the advice of the Sub-committee on Section-Work, the following circular letter was addressed to the Chairmen of the several Sections, in answer to which a number of very satisfactory letters have already been received

"In the endeavor to increase the interest in and concentrate the work of the special Sections, the Committee of Arrangements ventures to suggest to the Section Chairmen the advisability of selecting a I make use special subject for consideration on the first and second days of the meetings of the various Sections, to ang been bent at a right angle about 1½ inches from be introduced by two, or at most, three papers and the end. With the aid of a self-retaining usual and followed by general discussion, the remaining time to be occupied in the reading of other papers, pre-Medical Record, Jan 14, 1888), any portion of the sentation of specimens, exhibition of apparatus, etc.

"Should this suggestion be favorably received, the Committee begs an early response with specification of the subjects selected, names of referees to present the papers, and of members to open the discussions "

Two weeks ago a very largely attended meeting of the profession of this city was held at which vent was given to no little enthusiasm Liberal subscriptions to the entertainment fund poured in, and in the even ing it was established that the local profession would give their visiting colleagues a right royal welcome Thus far but two entertainments have been positively decided upon One, a grand concert at Music Hall, the other, a reception at the Art Museum, to be followed by a collation As time progresses other entertainments will doubtless be provided

The question that may prove a stumbling block in the way of the Committee is associated with the giving of the annual dinner We cannot accommodate more than three hundred (300) Will that many take the ticket at seven dollars (\$7 00) per plate? The "two kinds of tickets" clause of the mandatory resolution of the Association must be ignored on account of utter impracticability Some of the members of the Committee are inclined to give up the idea of the banquet altogether Others, however, are anxious to see it given, believing that if prominent men from the East and West were especially requested to attend, an excellent opportunity would be given those assembled at the board to bury past grievances, to dispel factional feeling, and in every way to strengthen the Association by restoring harmony

Joseph Ransohoff, Local Sec'y Com of Arrangements

Section on Medical Jurisprudence — The members that contemplate contributing Papers to the Section on Medical Jurisprudence of the American Medical Association, at the meeting in Cincinnati, May, 1888, are requested to forward the titles as soon as possible to the Chairman of the Section The following have already been promised

"Address by the Chairman of the Section," E M

Reid, MD, Baltimore

"Paralytic States, their Relation to Testamentary

Capacity," E C Spitzka, M D, New York

"Medical Jurisprudence in Relation to Wills," Richard Gundry, M D, Baltimore

"Expert Testimony in Medical Jurisprudence,"

Orpheus Everts, M D, College Hill, O

Feeticide, its Increase and Inadequacy of Law for its Prevention and Punishment," H C Markham, M D, Independence, Iowa

"Some Phases of the Civil Laws in reference to the Development of Man," J W C Cuddy, M D,

"Some Points in the Medical Jurisprudence of Insanity," E N Brush, M D, Philadelphia

"The Medico-legal Relation of the Inebriate to Society," I N Quimby, M D, Jersey City, N J E M REID, M D, Chairman

Baltimore, Md

NECROLOGY.

CHARLES M DUNCAN, MD

Charles M Duncan, M D, was born in Dummerston, Vt, July 1, 1808, died October 4, 1884 was the only son of Dr Abel Duncan, who was emphatically "the beloved" and successful physician of his day in Southern Vermont

Dr Duncan's boyhood was largely spent on the farm with his mother, with the advantage of attending the public schools and an occasional term at the academy His book, of which he was always fond, was his companion while engaged in farm work This occupation was uncongenial, and he found no difficulty in making choice of a profession Perhaps the desire to be like his father, whom he always heard spoken of as possessed of every manly virtue, aided him in his choice He commenced his medical studies with Dr Knapp, of Dummerston, attended lectures in Boston and Brunswick, Maine, taking his diploma at the latter place

In 1834 he located in Shelburn, Mass patiently for his work as the young physician must wait, meanwhile gathering about him solid and lasting friends In patient and self-sacrificing labor he laid the sure foundation for strong and enduring friendships in the hearts and homes of the people which few, in any profession, are so fortunate as to He soon took his place among the leading men of the town, and was ever identified with its in-For more than twenty years he served as town clerk and treasurer, and in general was sought not more as a physician than as a friend and coun-He became a member of the American Med-The community is to be ical Association in 1866 congratulated that is served by so earnest, faithful and conscientious a physician, by such upright and unswerving integrity in its business interests, and by one who proved himself so tender-hearted and sym pathizing a friend, for more than fifty years, as did the subject of this sketch. The action taken and resolutions passed by the Franklin Medical Society upon the death of Dr Duncan were fitting, and may be seen in the Boston Medical and Surgical Journal

THE DIFFERENTIAL DIAGNOSIS OF URÆMIA BY CHARLES W PURDY, MD, OF CHICAGO

HON FELLOW OF ROYAL COLLEGE OF PHYSICIANS AND SURGEONS, KINGSTON

It will be my object in this paper to draw the line as sharply as possible between those comatose states which are sometimes mistaken for uramia, and the I am the more willing to unlatter condition itself dertake this task, believing that the importance of the subject can scarcely be overestimated surely no uncommon experience with those who are engaged in active general practice to meet with cases in which men-especially those advanced in lifestate to which, unfortunately, too often death constiaged it has come to be looked upon almost as a mat-To the mind the thread of possibility, ter of course by which depends the lengthened skein of life, grows strands seem scarcely worth the efforts at strength-And thus the tears of friends, and perhaps the qualms of the scientific conscience are soothed must fall, so the aged must die

In a given case of unconsciousness of sudden onset, the result may be speedy death or recovery, depending very much upon the cause and the measures employed for relief And this brings us at once to in such cases

A number of conditions accompanied by more or less complete unconsciousness are to be met with that may be confounded with uræmia. It is important that the symptoms and signs of these various states study, for upon these we must often depend solely a few hours to several days or even weeks

able to readily construct the diagnosis from the symptoms alone

In order to differentiate accurately uramic coma from the various conditions with which it is sometimes confounded I shall first endeavor to draw a correct picture of the various phases of uræmia itself, and passing from this I shall consider the various conditions with which it is more commonly confounded, and lastly, I shall present in tabular form the chief features of each, that the observer may at a glance study their differential features

Without entering at present upon the much vexed question of the nature of the uræmic power itselfwhich still remains an unsettled problem—it should first be noticed that it usually expends its greatest force upon the nervous system, and therefore we must look to the nervous system for the most prominent manifestations of this disorder have been suddenly struck down in an unconscious as the central nervous system is concerned, it is a somewhat remarkable fact that the uræmic poison tutes the speedy sequel Indeed, so frequently is this usually acts upon the sensory and motor centres in picture presented to the professional eye, that in the diametrically opposite ways Upon the sensorium the tendency is towards abolition of function-and consequently tending to insensibility and coma, while upon the motor centre—the medulla—exaltaso brittle with advancing years that its individual tion or stimulation is produced - tending towards convulsions Coma and convulsions then are the most common results of the more intense action of the uræmic poison upon the central nervous system, by the reflection that as the leaves turn yellow they but in less intense degree of action the uræmic poison often seems to reverse this order—on the sensorium to produce excitement, delirium, etc., and upon the motor centre to produce a mild and transient paralysis This latter fact should not be lost sight of since in the first place it is perhaps not generally known the importance of an accurate and speedy diagnosis that uræmic coma and convulsions are often preceded by paralysis, and in the second place the occurrence of paralysis may lead the physician to mistake uræmia for apoplexy-more than one such instance has come under my observation within the past year

Uræmic coma is rarely of very sudden onset, but should receive the most careful consideration and is preceded by certain well-marked symptoms for from as data upon which to construct our diagnosis The most constant and prominent of these prodromata history and important facts bearing upon the case of course should not be lost sight of, since these fresensibility of the voluntary muscles, increasing drowsensibility of the voluntary muscles, increasing drowquently come to our aid opportunely in doubtful siness, more or less decided diminution of the volume Since, however, a state of unconsciousness of the urine, and a peculiar odor of the skin and precludes the possibility of gaining any definite oral breath-uræmic Among the less common prodromata information from the patient it becomes more neces- are, acute visual disorders, dyspnæa, distressing itchsary in these than in any other class of cases to be ing of the skin, restlessness by day and insomnia at night, delirium, deafness, paralysis, and convulsions

The headache is most often frontal or temporal if in reality he is rarely completely so in pure uramia the underlying cause be acute renal trouble, most often occipital if chronic—as cirrhosis or granular contracting kidney Headache is perhaps the most constant of all the early symptoms of urremia, and it is often very distressing. It may be distinguished from ordinary neuralgia by its non-conformance to the evening exacerbations so constant in the latter

Nausea and vomiting are scarcely less constant symptoms, and when present are often very obstinate and prevent the successful administration of medicine by the stomach The evaltation of reflex muscular sensibility is observed in the frequent twitchings of cer- laris responds to stimulants tain groups of muscles—most often those of the face The visual disorder may consist of acute amaurosis gutteral—the noise being made by the cheeks and -the patient becoming suddenly deprived of vision, or a more gradual and less complete impairment of vision may come on which is most likely to become hard and tense. The temperature is raised, marking permanent The first form is more common in acute renal disease, while the second form is more common if present it is more prominent about the malleoli in chronic forms of kidney affections dyspnœa occurs in two forms—the first closely resembling asthma, and the second due to pulmonary ædema and characterized by rapid respiration, 40 per minute or more A third form of respiratory disorder of not infrequent occurrence is Cheyne Stokes respiration—which should not be confounded with the more regular and uniform slowing down of the respiration due to large doses of opium

Restlessness is often very marked and not unlike the condition preceding delirium tremens, save that the apprehensiveness of danger so marked in the latter is absent The delirium—or mental intoxication —when present is peculiar in certain respects Upon fixing the attention of the patient closely he is usually | it is often the outgrowth of the same underlying cause quite rational, and replies to questions intelligently, but he is usually very forgetful-often repeating a most careful consideration question he has just asked and received a reply to

state, "these patients rarely sleep well" save under the influence of a narcotic

Paralysis is most common in the muscles of the face—usually of one side—and often involving the It often extends to the arm and leg pairment of sensibility in the affected part is rarely able complete even when the motor power is entirely the more trustworthy sign If the hæmorrhage occur abolished and rarely does it continue longer than twenty-four face may be pale but the general hue of the skin is

Let it now be supposed that the physician is called to see a case of typical uræmic coma, in which state the patient has been accidentally discovered and a hasty diagnosis is demanded The appearance of the patient is somewhat pallid This pallor is not the result of weakness of the circulatory forces as in syncope, but is rather due to some underlying renal disease It is therefore an unhealthy, partly cachectic pallor-familiar to those who see much of kidney pallor) occur chiefly in cases of early cirrhosis of the be bitten, but it is not deeply lacerated as in epilepsy kidney when the color of the skin may not depart in or in uræmia the least from the usual tint of robust and perfect health

Apparently the patient is profoundly insensible, Upon vigorously shaking the patient, or shouting in his ear, indications are observable that consciousness is not entirely abolished. He may indeed very often be made to speak, or to reply to questions asked in a loud voice—though usually in monosyllables If unable to do this there will at least be observable upon close inspection some expression of countenance indicative of perception, if not of comphension

Reflex sensibility of the voluntary muscles is still present and may be excited by percussion

The pupils are somewhat dilated and the orbicu-

The breathing is often stertorous, but not deep and lips not by the throat The pulse is increased in frequency—90 to 120 per minute—is rather full, often 100° to 102° F Œdema may or may not be present, The acute and eyelids

If the urine be drawn—and it always should be in doubtful cases—it will usually be found highly col ored, and to contain albumin The odor of the breath is characteristic—uræmic

Such are the more trustworthy symptoms of uramic coma, and they are essentially different from those of most other states of insensibility as will be presently

If to these we are enabled to add the history of the case, we shall have many of the premonitory symp toms already considered as additional guides

The condition most commonly confounded with uræmic coma is hæmorrhagic apoplexy and since as uræmia-vaso-renal change-it should receive

In recent typical apoplexy the insensibility if pres Insomnia is a prominent feature of the uramic ent at all is usually complete—it being impossible to arouse the patient or to elicit evidences of perception or comprehension This state may be reached gradually the same as in uræmia, though usually much The pupils may be contracted or di more rapidly Im- lated, and in this respect they are exceedingly vari-Inequality of the pupils-most common-15 The attack often lasts less than an hour in the pons varoln the pupils are contracted The respirations are increasingly usually normal stertorous and gutteral in character—the sound being made in the throat as in heavy deep snoring pulse is reduced in frequency, sometimes reaching 60 or even 50 beats per minute, and it is "labored " It is increased in volume and marked by tension temperature is usually subnormal, often marking 96° Paralysis is usually present of the hemiplegic There are rarely true convulsions with apo order plexy, the patient may fall and muscular spasms of Exceptions to this rule (the appearance of a clonic order may follow, and even the tongue may

It should be remembered that in apoplexy several of the more important symptoms vary with the stage

of the attack may be preserved and insensibility may come on After a few hours the clot may and often Perhaps the most conpulse and the temperature stant and valuable diagnostic symptom of apoplexy If actual paralysis cannot be made is hemiplegia out definitely, a close scrutiny will yet nearly always reveal "one-sided symptoms" of some kind If the arms be raised, for instance, and then permitted to In apoplexy it is reduced in the first stage drop, they do not fall uniformly

Since apoplexy from cerebral hæmorrhage is confessedly the most difficult of all conditions to differentiate from uræmic coma, it is proper that they now be considered side by side, as it were, in a compara-If the uramic coma be the result of chronic Bright's disease its history is often identical with that of apoplexy The patient is beyond middle age and well nourished The left ventricle of the heart is more or less hypertrophied, indicated by heaving impulse of apex beat, accented second sound of the heart most distinct near and to the right of the sternum in the second interspace, also extended area of cardiac dulness The arteries are hard—atheromatous—and the pulse is marked by sphygmograph Renal changes are almost as common in one case as in the other and, therefore, albuminuria will not form a safe distinguishing guide here The premonitory symptoms are much alike in each vertigo, visual disorders, epistaxis, drowsiness, pain in the head, and vomiting Indeed the very time of attack coincides, being most frequent after some unusually active or long continued exer-

Generally speaking the age of the patient is of service as an aid in distinguishing doubtful cases Thus, apoplexy is almost limited to middle and advanced life Albuminuma in the aged is for the most part due to contracting kidney-cirrhosis-and my own obervations have shown me that contracting kidney more often gives rise to convulsions without than with coma

On the other hand if the patient be under 30 years of age, apoplexy would be improbable, and uræmia would, moreover, be less likely to be overlooked, since it would then as a rule depend upon an acute renal disease, the symptoms of which could scarcely escape observation

symptoms of uræmia and apoplexy It has already characteristic indication of apoplectic coma. chief features are its completeness, permanency and one sided character—hemiplegic It comes on before or with the loss of consciousness, and it lasts through the attack with little or no variation and if the patient recover it is the last symptom to yield, often in fact becoming permanent Uremic paralysis as a rule precedes the coma for some hours or days It is transient, often lasting but half an hour, rarely than uremic longer than twelve to twenty-four hours, and conse-

Thus very early, the consciousness involving but the face or the face and arm I have in a few cases seen complete hemiplegia (motor)

The pulse in apoplexy is slowed in the first stage. does excite inflammation, thereby raising both the and usually does not become accelerated for many hours-until inflammation arises In uramia the pulse is accelerated from the first, before coma comes on. so that however early we meet with uramic coma the pulse is increased in frequency-90 to 120 temperature follows much the same course in each mains sub-normal for a variable time, always for hours, then it slowly rises, and in two or three days it may reach 100° to ro3° F

> In uræmia the temperature rises before coma comes on usually reaching to 100° to 102° F, and fluctuating between these points as the attack continues

> In convulsions due to uræmia the spasms are tonic, general, and usually repeated with more or less increasing frequency As a rule the convulsions precede, and are several times repeated before the appearance of coma, the latter coming on slowly and gradually, hours usually elapsing before its full devel-If unprotected, the tongue is bitten and opment often badly lacerated

In apoplexy, as previously stated, true convulsions decided increase in tension-well shown by the are rare, when present they are mostly clonic, rarely repeated, and precede the coma, the latter rapidly following the fall The tongue may be bitten but is not deeply lacerated In apoplexy the convulsions may be unilateral, in pure uræmia they are never so

The loss of consciousness in apoplexy is more rapid, more profound, and less variable than in uræmia An hour or so after the seizure, the patient is often completely comatose in apoplexy, and if he recover consciousness it most always requires several days for its accomplishment In uræmia unconsciousness creeps on slowly in a fitful, vacillating manner, and even after apparently complete unconsciousness is reached, there may be intervals of more or less consciousness until very late-near death In uræmic coma I have rarely found complete abolition of perception save very near death, and there is pronounced irritability of the voluntary muscles upon percussion In typical apoplectic coma abolition of consciousness is usually complete, and, moreover, when established the insensibility continues unchanged until death or general improvement occurs In apoplexy the respirations at first are as a rule easy and natural Sooner or later they become deepened, Passing now to a more minute analysis of the chief and finally stertor appears of a deep, noisy gutteral To one in an adjoining room the noise character been stated that paralysis is the most constant and very much resembles loud snoring. In uramia the Its respirations at first are also easy and natural Should cedema of the lungs be present, however, which is not uncommonly the case, the respirations become rapid—40 to 50 per minute Noisy stertor is rare in pure uræmic coma, and the little noise present is made with the cheeks and lips-a soft puffing noise Gutteral stertor may appear near death, as it often does upon the approach of death from many causes other

If any information of value is to be gained from quently is rarely present during coma While it is the pupils, it is mostly in the earlier stages of uremia one sided, it is rarely so extensive as in apoplexy-and apoplexy. In the former the tendency is to dilation of the pupils; sometimes, indeed, they are so widely dilated as to give rise to suspicions of bella- lepsy does not closely resemble uramia, save in the In apoplexy the pupils are very donna poisoning other contracted, or one pupil may be normal and it is only those cases of epilepsy in which the conthe other one either contracted or dilated Inequality is the more common feature forgotten that on the near approach of death from most causes, the pupils often become widely dilated

Having now reviewed the chief differential features of uramic and apoplectic coma, I shall next take up the subject of epilepsy, and note in passing the differential features of its symptoms from those of ura-First, as to the history It will of course be unusual to meet with a first attack of epilepsy, and therefore it will be generally known by the friends that the patient is subject to "fits"

Epilepsy is a disease of the young-75 per cent of the first attacks occur before 20 years of age The attacks are most common at night, unlike in The attack is always both apoplexy and uramia sudden, a few moments at most constituting the prodromal stage Convulsions always precede the coma, Consciousness is and they are of the tonic order completely abolished from the beginning, even before | scious, stertorous, comatose and anæsthetic The convulsions are rarely the convulsions begin repeated the same day, more often several days or weeks elapse before their return In uræmia, it will be remembered, a few hours at most elapse between In epilepsy conthe convulsions when repeated sciousness gradually returns after the convulsive attack, the average period of coma being about one consciousness, since epilepsy or apople y sometimes hour, unless the attack occurs at night, when it is In uræmia unconsciousness does not much longer usually occur until after several attacks of convulsions, and it gradually deepens instead of wearing away after the fits

The coma following the epileptic convulsions is much like a sound sleep, after the first few minutes, as a rule, the patient can easily be aroused There is rarely true paralysis and, when present, it is probably due to cerebral hæmorrhage It is true there is nearly always more or less loss of power after an epileptic convulsion, and in the arms and limbs this may be apparently complete, but it wears away in a few minutes or hours, being a weakness or prostration rather than a paralysis The coma of epilepsy 15 most often a confused mental state from which the patient to some degree of consciousness by shaking steady stertor, "coming and going," guttural in tone, give his name and address, and if so it is to be noticed patient may be easily aroused There is usually unand the unconsciousness varies greatly both in intensity and in duration In epileptic coma reflexes are not abolished, the pupils are normal, the conjunctiva is sensitive, and the orbicularis responds is usually bathed in perspiration—at first warm, dusky and purple, but gradually cooling and becoming pale

The temperature does not vary much from normal, temperature may rise above 100° F

The pulse in epileptic coma is rather small and creased in frequency If a tracing be taken with the to be able to speak, the articulation is thick and in sphygmograph it shows the features of dicrotism It distinct This indicates a disproportionate action

will be seen from the foregoing description that epiconvulsive seizures, and these are strikingly similar, Sometimes one pupil is dilated and the except in their frequency of repetition Practically, vulsions are rapidly repeated, and the coma conse-It should not be quently deep and prolonged, that are likely to be confounded with uramia Happily, such attacks are rare, and for the most part due to traumatic causes which rarely escape attention

We have next to consider the coma depending upon alcoholism, often one of the most difficult con-There are, indeed, few ditions to diagnosticate states of unconsciousness with which it may not be Drunken stupor has even been misconfounded taken for syncope and, strangely enough, the unfortunate patient has been made to swallow brandy for The coma of drunkthe purpose of reviving him enness varies in intensity according to the dose of alcohol taken, and the susceptibility of the patient to There may be only quiet stupor, from its influence which it is easy to arouse the perceptive and voli tional powers of the patient, or all the senses may be abolished, the patient being completely uncon-

In typical drunkenness the breath is usually loaded with alcohol, and this is readily recognizable by the It is especially so if the debauch be due to The odor of alcohol in the breath, while it is a strong presumption of drunkenness, yet must not be absolutely relied upon as the cause of un supervenes upon a fit of alcoholism

The respirations are heavy and often stertorous in The stertor, when present, is variable drunkenness The respirations are deep drawn and intermittent The stertor is simi and less frequent than normal lar to that of heavy sleep The expression of counter nance is vacant, sometimes the features are suffused and bloated, the lips are livid, the pupils are dilated,

and the conjunctiva is much injected

The pulse is small and rapid, and the heart's action The temperature is usually subnormal is feeble The skin is usually covered with cold, clammy per-Vomiting is common, and evidences spiration thereof should be sought for about the mouth or clothing In some cases it is possible to arouse the or pinching him that the articulation is thick, drawling and indistinct He awakens confusedly and relapses again into ap-Sometimes, however, the patient be The skin comes irritable upon disturbance and indulges in This is often the diagnostic sign relied upon by the police patrolman, who seeks to elicit it by sharply striking the sole of the shoe with his baton, an excellent means of exciting reflexes, but an un however, the convulsions be rapidly repated, the trustworthy diagnostic of alcoholism, since patients in apoplectic conditions will sometimes resent such disturbance both verbally and muscularly. It has been stated that if the patient be aroused sufficiently

of alcohol upon different centres of the nervous sys tem, which is often very marked

Tactile sense and motion are usually in reality more disturbed than is cerebral perception and consciousness In other words, coordination of muscular action and special sense are more impeded than The patient often reasons so well! is cerebration with himself that he requires to be told that he is drunk, unless he attempts to walk, when difficult coordination of muscular motion teaches him that The medulla and spinal cord. he is intoxicated therefore, are more deeply anæsthetized than is In certain individuals these featthe cerebrum ures of alcoholism are especially prominent, indeed, in such the intellectual faculties are actually sharpened, even when motor coordination is greatly In such cases most brilliant reasoning powers are manifested or able speeches delivered even though the subject be unable to stand without It will be remembered that, in describing uræmia, it was stated that the uræmic poison tended to a directly opposite action upon the central nervous system, viz to stimulate the spinal system and medulla, and to depress the cerebral centres If, therefore, the patient can be in a measure roused, these distinguishing features should be carefully observed in all doubtful cases

Dr von Wedekind has recently brought forwards a new test of drunkenness for which he claims "infallibility " "By simply pressing on the supraorbital notches with a steadily increasing force you may, with certainty of success, bring an unconscious alcoholic to his senses, and thus differentiate on the spot between alcoholic and other comas " Incredible as this may at first sight seem, Dr von Wedekind has brought forward a record of 137 cases of alcoholic coma gathered from the ambulance service in which his test has been applied, and in the nine cases of failure of the test out of the whole 137, each one was accounted for by subsequent discovery of some additional cause of the coma

From what has been already stated as to the action of alcohol upon the central nervous system, it would be expected that convulsions would be rare from this cause, and such in fact is the case A single convulsion does sometimes occur during, or more frequently preceding alcoholic coma, but rarely are convulsions repeated in pure alcoholism as in epilepsy or in

It seems necessary, in passing, only to mention the possibility of confounding syncope or hysteria with uramic coma These affections are so familiar to those in general practice, and the symptoms are so well known, that they are not likely to be mistaken for any of the states already considered In syncope return to consciousness is so complete, that nature soon reveals the diagnosis, while in hysteria the symptoms, though exceedingly variable, yet possess a general definiteness familiar to all It remains, therefore, but to consider the subject of poisoning as contrasted with uraemic coma Although various narcotics produce a state of insensibility and coma,

as well as death in large doses, the effects of opium alone will be considered here, since it is the narcotic for the most part selected for destructive purposes, as well as the one, from its wide range of use, which most commonly gives rise to accidents

The physiological action of opium and its preparations upon the human organism in medicinal doses is well known It is only with the larger doses-approaching lethal-that we now have to do, since it is only the deep narcotism induced by decided doses that constitutes the coma likely to be confounded with uramia

In coma due to opium the patient may be aroused sometimes to a greater or less extent, but quickly lapses into stupor In late stages it is difficult, if not impossible, to rouse the patient The pupils are minutely contracted and insensible to stimulation The respirations become slower and more shallow, generally feeble, and sometimes stertorous may become reduced to 10 per minute or under The frequency of the respirations is perhaps the best gauge of danger, since in most cases of death from opium the direct cause is asphyxia from paralysis of the respiratory centres The odor of opium is usu-The pulse is slow and ally present in the breath feeble, the face is shrunken, pallid, cyanosed, and The eyes are heavy and the expression is ghastly The skin is warm and moist with the lips are livid perspiration, and often intensely itching, especially about the nose

In differentiating the coma of opium from that due to other causes, the special features to be noted are, first, the contracted state of the pupils almost pathognomonic, and is only absent at the approach of death Hæmorrhage into the pons Varolii, as first pointed out by Wilks, induces a similar contraction of the pupils, but this is almost the sole morbid state that produces the uniform and extreme contraction of the pupils similar to opium narcotism Second, the slowing down of the respirations is almost characteristic of opium coma. It is to be borne in mind that, in the early stage of opium narcosis, the respirations are rather hastened, eventually, however, if the dose be large, the respirations become decidedly Cheyne-Stokes' respiration, which is less frequent very common in uræmic states, should not be mistaken for retarded respirations due to opium distinction is easy, and it is only necessary to mention the possibility of mistake to guard against it

Convulsions are rare from opium. In many of the lower animals the action of opium constantly tends to produce convulsions, but in man this result is chiefly confined to children The history is important mostly in an exclusive way—the symptoms of the states already considered, as a rule, being absent especially the unconsciousness is so brief, and the Aside from this, opium poisoning is most frequent in the young

It should be borne in mind that, in the consideration of the various states of unconsciousness described in this paper, the aim has been to depict the more trustworthy features of typical cases Variations from these types are to be met with, even in uncomplicated cases, which tax the skill of the most acute diagnostician

Special Features	Unconsciousness not com plete peculiar odor of breath consulsions re curring frequent pulse temperature increased albuminuria	sensibility unequal pu	unconsciousness not	present injected con	um breath, slow res pirations cyanosis

It should likewise be remembered that two, or even | suffering but little from shock, pulse 90, tempera three of the causes considered may combine to pro- ture normal, no pain duce a given state of insensibility, thus bringing about large bullet wound half an inch below umbilicus, and considerable confusion of the symptoms patient the subject of granular kidney-interstitial make laparotomy, and assisted by Dr E W Lee, nephritis—may take a dose of opium, the tendency of which will be to suppress the urine, and uræmia may be the result convulsions may induce cerebral hæmorrhage, since all the conditions are favorable to such result in patients with granular kidneys. In such a case we have the symptoms of apoplexy added to those of uræmia, which latter, in turn, arose from the effects upon the kidneys of the opium Again, the ingestion of a large dose of alcohol may precipitate an attack of convulsions in an epileptic subject, and in turn the convulsion may lead to cerebral hæmor-The possibility of mixed cases should therefore be kept in mind Happily, such cases are comparatively uncommon, but when they do occur they are only to be detected by careful study of the leading symptoms of each stage of the attack, since one cause usually supervenes upon another, rather than all occurring simultaneously

In conclusion, it is hoped that the appended differential table may aid the diagnostician by presenting at a glance the leading features of each of the comatose states considered in this paper

GUNSHOT WOUNDS OF THE ABDOMEN

Read before the Chicago Pathological Society Feb 13, 1888 BY I B MURPHY, M D,

OF CHICAGO SURGEON TO COOK COUNTY HOSPITAL

at 8 PM, June 16, 1886, suffering from a bullet domen filled with blood. The suture in post-pen-Case I —H M, age 26, admitted to the hospital I saw him at 10 P M wound of abdomen

On examination, I found a Thus, a an inch to the right of median line I decided to and the House Staff of the Hospital, I made the median incision three and one-half inches long Furthermore, repeated uræmic | began by examining the small intestine and repairing each wound as it was exposed by first paring off the ragged edges with a scissors, then inserting a con tinuous catgut suture in the mucous membrane, then in the peritoneal covering, the first row of sutures being entirely covered by the second was continued until the eleven openings were united I found that the bullet had passed through the posterior peritoneal wall close to the pelvis of left kidney, cleansed the peritoneal cavity with a warm 1/2 per cent carbolized water, united the abdominal peritoneum behind with catgut, also the opening made in the anterior peritoneal wall by the bullet, sewed the peritoneum at the incision with a continu ous catgut suture, the muscular wall with deep silk suture (interrupted), dressed the parts with iodoform gauze, then carbolated gauze and borated cotton Operation lasted two hours, patient's condition good after the operation was completed, pulse 110, and of good volume

The following morning the House Surgeon re "No vomiting, patient slept the greater part of the night, did not complain of pain, pulse 110, temperature 991/2° F, no thirst or tympanites 7 PM pulse 96, temperature 99° F No vomiting and no pain, says he is hungry " I called at the hospital the following morning and found that the patient had died suddenly at 7 30 AM, after spend-At 6 AM he coming a quiet and painless night plained of weakness and said he was fainting

Autopsy - Found heart and lungs normal, ab He was toneal wall torn through, a large quantity of blood in renal artery from which the hemorrhage came

The wounds in the intestines were all completely united, being both air and water tight, in the majorthe patient only lived thirty-six hours after the operation, the peritoneum had already restored itself, and made the openings impervious. No evidence of beginning peritonitis Cause of death hæmor rhage from renal artery

Case 2 -G J, colored, aged 22, admitted to hospital May 24, 1887 Said he was shot in the ab-

domen about two hours previous

On examination, a bullet wound two inches to right of median line and an inch above umbilicus was found, dulness in the lower portion of abdomen Pulse 66, of good volume, some shock I decided on an exploratory incision, found the abdomen full of blood, the bullet passed from the abdominal wall substance almost directly backwards and into the The hole in the posterior surmuscles of the back face of the liver could be felt by passing the hand around the liver There were no perforations of either stomach or bowels The abdomen was cleansed, about two pints of blood and clots removed, the hæmorrhage had ceased The opening made by the bullet in the abdominal wall was closed with catgut suture from the inside, abdominal peritoneum united with catgut suture, and the muscular tient since, and he is feeling as well as he ever did wall and skin with silk Dressed antiseptically Operation lasted thirty minutes Patient in good condition

May 25 Slight tendency to vomit during the night and some pain, but feels well this morning The patient's temperature did not reach 99° from apparently penetrating down and in symptom until June 3, when he complained of pain in the back, and on examination a small swelling just over the supposed position of the bullet was He was anæsthetized and the bullet re- from shock moved, also a small quantity of pus Convalescence was rapid and patient was discharged June 13

ing fifteen feet in front and a little to the right one-half inches in front of the axillary line shock, wound had been probed before patient came tures to hospital

Three hours after the injury patient was anæsthetof an inch from its lower margin, also perforating on the back above the crest of the ilium the transverse colon on its convex portion about tion lasted 70 minutes, patient very much collapsed one-half inch from its beginning, leaving a bridge of

the retro peritoneal region, an opening in the left point of entrance and exit, then passing into the muscles of the back an inch to the right of the spine.

The bridge of intestine between the two openings was cut through, the edges of the wounds freshened, ity of these the catgut could not be seen on account | making an opening about one an one-half inches of the deposit of reparative material placed about in length. The mucous and muscular layers were them No evidence of impending gangrene Though first united with a continuous catgut suture, the peritoneal covering was then sewed over it with a continuous catgut suture, about half a drachm of fæcal matter escaped from the intestine after the opening was enlarged, but none before Abdomen cleansed with boric acid solution, and blood-clots Parietal peritoneum united with continuous catgut suture Muscular and continuous tissue united with interrupted silk suture Dressed anti-Operation lasted about three-fourths of septically an hour Patient came from the operating table in good condition, pulse 90, and of good quality. 7 30 PM, pulse 78, patient vomited considerable in the afternoon, some pain in the wound

August 24 8 AM, pulse 72, temperature 99°; into the margin of the liver, passing through its slept considerable, ordered 1/2 ounce doses of brandy every two hours with carbonated water pulse 76, temperature 100 20, vomited up to 4 P M,

but not since, feels hungry and thirsty

August 25 AM, pulse 74, temperature 98 5°, slept well, no vomiting From this time on the patient made a rapid recovery The first dressing was removed September 2, complete primary union Sutures taken out and wound redressed Patient discharged cured September 16 Have seen the pa-

Case 4 -] H, aged 26, was admitted to Cook County Hospital on December 1, 1887, at 8 30 A M, for gunshot wound of abdomen On examination a wound was discovered on the right side nearly in the axillary line, and just below the costal cartilages, that time on, nor did he have a single untoward the onfice were blackened and powder-stained, and another opening on the left side midway between the costal cartilages and the level of the umbilicus, was found The patient was suffering profoundly

Under ether, and after the patient had valked two miles, the wound on the right side was enlarged, Case 3—Geo S, colored, aged 57, musician (but when it was found that the bullet had entered the more of a drunkard) by occupation, admitted to hospital August 23, 1887, at 3 PM Was shot with a 38 the liver in its downward course. The usual median course and the liver in its downward course are the state of the liver in its downward course. calibre bullet a few hours before, his assailant stand-incision was made, revealing two wounds in the The stomach with extravasation of food into the abdobullet entered on a level with the 9th rib, one and men (small quantity), and one in the mesentery, Urine some bleeding from the latter These were all carecontained no blood Pulse 78, full and strong, no fully sewed up with deep and superficial catgut su-The intestines were drawn out and enveloped in warm towels No wounds were found in The peritoneal cavity was thoroughly washed them ized, and an incision was made three inches long out with warm solutions of boric acid, and the indownwards and inwards from the point of entrance cisions sewed up with silk after securing the peritoof the bullet towards the umbilicus The bullet was neum with catgut A rubber drain was passed found to have passed through the liver three-fourths through the wound on the right side and brought out

Through an error the patient was given two hypointestinal tissue half an inch in length between the dermic injections of one third grain of morphia, and he showed severe symptoms of opium poisoning, and did not become conscious until 6 PM, some eight nours after the operation. The pulse became At 9 PM the patient berapid and more feeble came delirious and died at 11 30 P M doubt that the opium contributed somewhat to the remarkable cases are threadbare from being quoted unfavorable outcome in this case, also the prolonged operation Autopsy showed the abdomen case of this kind and say, "Nature will have nothing clean and no blood in it

REMARKS —There are no positive symptoms of perforation of the stomach or bowels, ie, if we do not consider the mere fact that a bullet passed through the abdominal cavity per se a positive symp- rotomy, and the bowels examined, but he says, "if a tom of perforation of the viscera or one of the large portion of the bowel protrudes from the opening and vessels And that we should so consider it is proved is not wounded, it should be returned and the open by the results of Dr Parkes' experiments in 38 bulling sewed up." He goes just half way in the right let wounds of the abdomen in dogs, in which only two escaped injury of the stomach and bowels, and McCormac tell but that the bowel may be wounded in one of those there was considerable hæmorrhage, making only about 2 5 per cent in which the viscera bullet? Not any more than he can tell from the ex which we act and consider it pathognomonic where tions there are in the bowels, and that it would be a greater percentage of the cases conform with the absurd for a man to attempt the latter is thoroughly us in the face, is it not the height of presumption periments of Dr Charles T Parkes on dogs He for us to hope that the viscera are not injured after has opened up the field in a most thorough manner, a bullet has traversed the abdomen? Indeed, the and demonstrated to us what can be expected from symptoms of shock were only slight, except in two a bullet passing into the abdomen If we will not cases, and in one of them it was due to hæmorrhage

In Case 4 there was no vomiting of blood to indicate a wound of the stomach At the International Medical Congress it was suggested by the first speaker on that subject "that no operation should be performed until such time as fæcal matter appeared at the external wound " This, of course, is absurd, for the food of fæcal material does not escape from the bowel at once after the injury, but it is principally on manipulation that we get an immediate escape, , a primary escape of the contents of the alimen

Nature prevents this escape by an ecmucous and muscular coats plugging Dr Gross states that gs temporarily in all cases," but he does on takes p me that elapses before it the p e bow fluid eight hours after the shooting of perforating wounds hen not?

> e shot through the abdomen | median incision sian war, five cases of recovery are mal position as possible, and not expose them to the

reported in one corps, but I cannot find any report of the number of deaths Larrey, in a long experience, reports only one case of penetrating wound without immediate serious results, and afterwards There is no the bowels were found to be contused These few Abernethy used to shake his head when he had a to do with wounds of the small intestines" Bell says, "We announce them as fatal" Sir William McCormac says that in cases of perforation the me dian incision should be made as for any other lapa How can Sir William direction and then falters three or six inches from the point of entrance of the Is there any other sign in surgery upon amination of the external wound how many perfora None that I know of With this fact staring demonstrated by the excellent and well known ex act it is our fault Ostrich-like, shall we stick our heads in the sand?

The light that has been thrown on the subject from numerous experiments, and the results follow ing the treatment of cases influenced thereby, puts us in a position where we cannot escape the respon sibility from the charge of malpractice, when we stand idly by and allow our patient to sink from a septic peritonitis or bleed to death from a wounded We, as scientific men, should act fearlessly, and having done so we have the consciousness of having fulfilled our whole duty

All the preparations should be as thoroughly anti septic as for laparotomies for other diseases, ie, the disinfection of hands, instruments, etc

The first incision should be to enlarge the opening f the stomach as well as made by the entrance of the bullet down to the pa not more than a drachm rietal peritoneum, to be sure that the ball entered , notwithstanding the stom- the abdominal cavity, and that it did not rest on the uantity of food, the two peritoneum, as it did in a case of mine it the index finger, and the incision should be, in the majority of cases, made in the median line, as it allows of a greater latitude for riments fæcal matter did not the examination of the organs, but in some cases it g in a single case This will be impossible to bring the wounded bowel to ening by the mucous the opening in the median line heardy appearance of is outside of the mammary line the incision should be over the entrance of the bullet, and enlarged from There are that point as may be deemed best,—that is, in large, In all of my experiments upon rted of perforating broad-bodied men ere the patients recover the cadaver I was able to reach the wounded bowel in the most remote parts of the abdomen from the median incision. The examination of the organs In the late rebel- should be methodical and rapid, beginning with the ypenny, as his surgeon records it, cæcum and examining the small intestines upwards, driven plump through his guts " In being careful to keep the bowels as near their nor

exit opening in the peritoneum can be found, sew it with silk to prevent a return of pus into the abdom-The number of openings in the bowels wounds may vary greatly, and too great care cannot be exand remain open, causing a fatal outcome

Should the mesentery or omentum be wounded great care must be exercised in ligating the vessels around the opening by suturing the proximal side of the mesentery with catgut, using a full curved round the serosa in its entire circumference between both layers of peritoneum in the mesentery

Another important point is to look for hæmor-linsure adhesions (Dr Senn) ball makes its exit from the peritoneal cavity Should there be oozing from this opening it should be enlarged and the vessels closely examined, and if injured or oozing ligate them Had I done this in my first case, I am quite sure the fatal hæmorrhage would have been avoided I may also mention a case in the hands of one of my colleagues where fatal hæmorcellular tissue in the neighborhood of the left kidney The patient died of exsanguination on the third day Autopsy showed the source of the hæmorrhage, also that the patient had no peritonitis

The suture to be used is one that (1) can be easily surfaces in position for forty-eight hours without their position causing a pressure atrophy, (3) that no suture that shall be as little tension on the suture in the peritoneal layer as possible, (5) they shall be aseptic, (6) they shall diminish the calibre of the bowel as and spread the omentum over the bowel little as possible, (7) serosa shall come in contact

The materials that at once suggest themselves to fill all the requirements are chromated and juniper catgut, softened in carbolized water and sublimated silk (1 1000) I used carbolized catgut in my cases, found shock but since that time the reports of Professor Theodore Kocher's experiments and operations in Berne, have convinced me that catgut prepared in carbolized oil or alcoholic solutions of the same are not reliable and frequently septic The details of the same can be found in the Correspondenz-Blatt fur Schweizer Aerste, and are well worth perusal The best mode of insertion to supply the above mentioned requireinserted very rapidly, and the tension on the serosa is lessened by the approximation of the mucosa, it will remain unaltered forty-eight hours and not

air, repairing each opening as it appears If the exposed on the mucous surface, as in Jobert's suture, but it would diminish the calibre of the bowel in transverse wounds, and for that reason, and that inal cavity, should any form in the tract or around only, is Lembert's suture used in large transverse

A portion of the bowel must be excised when more ercised to make certain that none escaped notice than three-fifths of its calibre is destroyed, otherwise there will be a stricture at that point This can readily be accomplished by invagination with a rubber supporter in the intussusceptum, as suggested by Dr N Senn, and a continuous suture approximating This may be needle (Czerny), also removing all blood clots found further supported by the plastic operation on the omentum to support the bowel in this position and When there are two rhage in the retro-peritoneal cellular tissue where the large openings which can be approximated and leave a fistula, allowing the contents of the bowel to pass through the fistula and the loop of bowel to be retired (if the loop is short, that is, less than four feet in animals), the openings should be approximated by Dr Senn's bone-tablets, or by the suturing process suggested by one of the surgeons in the late Rebellion Dr Reybard's wood-plates may be used and the rhage occurred from a vein in the retro-peritoneal opening approximated to the abdominal parietes The danger when the bone- and wood-plates are used is that they cause pressure atrophy These advantages are (1) the rapidity with which they can be inserted, Dr Senn claiming that he can close the opening in ten minutes, (2) the certainty with which they and rapidly inserted, (2) that will keep the serous approximate the serous surfaces and retain them in

Totlet —Remove the blood-clots and escaped conis exposed on the peritoneal side of the bowel shall tents of the viscera with a sponge, wash out the pass through to the mucous surface, (4) that there abdomen with a solution of boric acid until such time as it returns clean from the external wound, replace the bowel as near the normal position as possible, fear there is still remaining foreign matter, it would be better to put in a Mikulicz drainage than to lose much time in trying to cleanse the abdomen and producing a great degree of shock from which the patient cannot rally Above all things avoid pro-

THE EFFECT OF OPIUM ON THE UNBORN CHILD BY C E RUTH, MD. OF MUSCATINE TOWA

Opium is at once one of the oldest and most useful of drugs, as well as one of the most potent agenments are (a) in longitudinal and small transverse cies for harm Its well-known capacity for relieving wounds, a double row of continuous sutures with a pain of almost every variety and grade of severity round (Czerny) needle, the first approximating the has resulted in its almost unrestricted use where the mucosa, and the second the serosa, the latter cover- relief of pain is a prominent indication in the treating the first from sight, (b) in large transverse wounds ment of disease Its property of relaxing both volthe Lembert suture should be used The first can be untary and involuntary muscular fibres, as well as the relief from pain, has resulted in its employment very largely in threatened premature deliveries

But there are at times contra-indications to its use cause pressure atrophy, and the serosa unites in from and limitations in its utility, especially its remote eftwenty-four to thirty-six hours, as shown by e, peri-fects These we too frequently lose sight of or disments on animals, and in my first case The contin regard Authorities lay great stress upon care in the uous suture exposed on the serous surface is not administration of opium to very young children, but

where can be found anything in regard to its effects on the unborn child when administered to the mother? We are told that Too of a grain of opium has produced convulsions in children, and death by convulsions has been produced by very minute doses, also that the very young child is proportionately much more susceptible to the action of opium than the adult, but is this susceptibility just developed at birth or does it exist before? I think it exists before birth, and that it is as strongly marked as it is after delivery, and in the absence of the slightest evidence to the contrary will proceed to furnish the evidence for my views, which are based on evidence elicited from observation of the effect upon the unborn child of the administration of large doses of opium to pregnant women for painful neuralgic affections, including gastralgia, and in threatened premature labor The question would be immediately asked, what evidence could you obtain of any effect upon the unborn child? We are told that opium produces convulsions and death by convulsions in young children, then, may not the unborn child have convulsions when we overload the blood circulating to its unstable nervous system with a poison whose characteristic effect, in but a few hours at least, in case birth should take place, is conceded to be the production of convulsions?

In case convulsions do occur in utero, have we any possible way of determining the fact? Given a case of advanced pregnancy in which the physician is administering large doses of an opiate to the mother, and she begins to complain of tremendously violent motions of the child, such as she never knew before, and the physician, by placing his hand on the abdomen, detects motions of the child apparently many times more violent than usual, and so severe as to cause the mother to scream aloud in agony and say the movements are unbearable—this is repeated in numerous cases, and he then remembers the characteristic effect of the drug on young children, then he finds that these powerful motions in each case accompany the full effect on the mother of the administration of large doses of opium, it seems to me we are very slow in reasoning from cause to effect if we do not come pretty soon to some opinion in regard Do we get a sufficient amount of to their relation opium into the mother's circulation in administering full medical doses to her to send a proportion large enough to the child to produce an effect on the child in utero that Top of a grain has been known to produce on the child soon after delivery, provided they are equally susceptible in the two states? Estimating the weight of the mother at 120 lbs, and the child at 6 lbs, we have the child near birth representing about 20 of the weight, and if we give opin gr iv, at once or in divided doses near together, we have 1 gr of opium for the child's proportion of the gr 1v Tho of a grain may produce convulsions in a young child after birth, may we not justly conclude that & of a grain is very liable to produce the same result in the unborn child, especially when it is substantiated by such evidence as previously mentioned?

If the child receives through the mother a much larger quantity than we would think of giving it after

birth, should we not carefully consider the possibility of producing convulsions and death in the unborn babe by administering anything like full doses of an opiate to the mother? The proportion of opium which is the child's share being so large, of course we must conclude that unborn children are daily getting poisonous doses of opium. In the prevention of abortion most authorities recommend opium as the sheet-anchor, but those of us who have used it for that purpose know too well how seldom it has given satisfaction in preventing premature delivery

Let us consider for a moment, in each threatened abortion case, the possibility of producing the death of the fœtus, and certain abortion following the use of the very remedy we are using to prevent the same We certainly have no reason to believe that the in creased susceptibility of the child to the action of opium is just developed at birth, but, on the contrary, have good reason for believing that it is still more strongly marked in early pregnancy, when we know that the number of abortions occurring during the administration of opium for their prevention is In my practice the number of abortions very great occurring during its administration is as great as with rest in the recumbent position with the hips elevated, etc, without the use of opium

I conclude that opium will not prevent abortion, that it may be and probably often is an important factor in aiding or rendering more certain the completion of an already threatened abortion by causing

convulsions in or death of the child

When opium is administered to the mother for other painful affections, when there is no threatened premature delivery, is the death of the fœtus as fre quent as the sized dose would lead us to suppose? Bartholow says that opium causes death through pa ralysis of the muscles of respiration, thereby depriving the patient of the amount of oxygen necessary to sustain life, and sometimes, he says, death is caused by paralysis of the heart Anyone can at once see that death by paralysis of the heart is the only one of these methods applicable to the unborn child, and that for that reason alone death in utero does not occur more frequently than it does from administra tion of opium to the mother, for as long as the mother, who is least susceptible to its action, still continues to breathe, oxygen will be supplied to the child if its heart still continues to beat of the fœtus has not the resistance to overcome in the lungs, by want of oxygenation of the blood, which the child has after birth This, then, will account for the small number of deaths from administering opium to pregnant women when labor is not threatened or in progress, and will also account for the relaxed con dition and feeble hold upon life that children have when born while the mother is considerably under the influence of an opiate For, the moment a child is born, whose blood is already charged with opium, so soon do the influences of paralysis of the muscles of respiration manifest themselves, rendering the respiratory efforts feeble or entirely absent, and greatly lessening the child's chances for an independent existence

December 12, 1887

CYSTIC KIDNEY AND OVARIAN CYST IN THE SAME OVARIOTOMY AND RECOVERY INDIVIDUAL

> BY THOMAS W KAY, MD, SURGEON TO THE JOHONNITIS HOSPITAL, DETREUT, SYRIA

Répéka, a virgin, 15 years of age, of Armenian parentage, was brought to me, July 8, 1887, from Adana, with the following history From the first appearance of her menses till five months previous to her visit to me, the menstruation had been free and regular, and with but little discomfort. At that time she was confined to her bed with neuralgic pain in the right ovarian region After several days of a scanty flow of menses the pain left, but returned with ticed a swelling in the right inguinal region, which was only slightly less in size than at present Since time is greatly increased at the menstrual period, radiating from the swelling over the whole abdomen Three months ago she was aspirated by a physician and nearly two tumblerfuls of watery fluid drawn off The fluid did not change its color, and gave no pre cipitate on boiling The aspiration diminished the size of the tumor, but only for a few days

On examination I found an uneven, slightly flattened, oblong tumor, as large as two fists, situated in the right inguinal region. It gave no sense of fluctuation and was very slightly movable A small scar over it showed the point where the aspirator needle had been inserted By vaginal examination the uterus was found of natural size, freely movable, and occu-The left ovary was not pying a normal position enlarged, but the right one could not be distinctly

made out from the vagina

Though there were serious doubts about the case being an ovarian tumor, I decided to perform laparotomy and be prepared for ovariotomy if necessary After several days of preparatory treatment, I operated under all antiseptic precautions, except the spray On opening the abdominal cavity I found symptoms of a previous peritonitis, the omentum being adherent to the intestines in many places The slightly movable tumor was covered by the intestines, and unnecessary suffering to the patient proved to be the right kidney, enlarged and displaced It was probably cystic, but that could not be clearly made out, the intestines and mesentery being adheraspirated, which was probably the cause of the pentonitis Below this was found a cystic ovary as large was bound down by inflammatory material cyst was a large as a hen's egg, and there were several has been involved smaller ones The left ovary was normal in size and After applying a double of healthy appearance ligature the ovary, with the end of the tube, was removed and the abdominal wound closed, being then dressed with iodoform and antiseptic cotton The well, having had her menses without any pain

This I believe is the first ovariotomy that has been performed in Palestine or Syria

Ovarian tumors among Eastern women are very rare, this being the only one that has come under my notice during a five years' residence

MEDICAL PROGRESS.

THE USE OF THE VAGINAL TAMPON IN THE TREAT-MENT OF CERTAIN EFFECTS FOLLOWING PELVIC IN-FLAMMATIONS -In an article on this subject, read the menses, after forty days, at which time she no-before the Alumni Association of the Woman's Hospital of New York, DR T A EMMET says

Under what conditions are we likely to obtain the then her menses have been very irregular and scant, best results from the use of the hot-water vaginal inand the pain which is present, more or less, all the jections, and when might we expect a good result from the uniform pressure which will be exerted by properly tamponing the vagina? No other mode of treatment yet known can accomplish so much as is gained by the use of the hot-water vaginal injections in all acute pelvic inflammations The hot water acts as a poultice in exciting contraction of the arterial capillanes Its continued use can diminish the circulation in the parts with which it is brought in contact, as is done in the hands and arms of a washerwoman while in the exercise of her vocation Nearly thirty years ago I recognized the fact that the reaction from a continued application of heat was contraction in the muscular coats of the arteries, and hence its application and value in lessening the supply of blood going to the seat of an acute inflammation The use of the hot-water injection is invaluable in the treatment of all stages of inflammation involving the cellular or connective tissues of the pelvis, in lymphangitis, in phlebitis, and in the early stages of On the other hand, the vaginal pelvic peritonitis tampon, in my experience, has only been beneficial after all acute symptoms have subsided If this one feature is not recognized as a cardinal point, the indiscriminate use of this means of treatment will always be attended by unsatisfactory results, and with much

The only class of cases in the treatment of which I have derived any special benefit from the use of the vaginal tampon has been where I have supposed the ent to its anterior surface. It had undoubtedly been blood-vessels had degenerated into a varicose condition, and where this state of the veins has been brought about, as I have shown, from the effects of as an apple, to which the end of the Fallopian tube local peritonitis with adhesions, from the loss of the One connective tissue, and from injury where the fascia

Let us now consider the use of the tampon in the condition I have described as being the one fitted for its action I have laid down the rule that its use can accomplish no good, but may do much harm, so long as any inflammatory symptoms can be detected girl made an uninterrupted recovery, and in three We must trust to the use of the thermometer to show weeks left the hospital to make a pilgrimage to Jeru- the absence of an elevated temperature in the pelvis, One month later she came to see me on her and to the want of other symptoms indicative of existway to Adana and reported that she was entirely inginflammation. In the absence of other symptoms we must exclude to a great extent the presence of pain

on pressure as an evidence of active inflammation, its chief value then being but an indication of the complished unless these diverticula are destroyed manner in which the tampon should be applied

Where adhesions have formed and the natural elasticity of the tissues has been impaired, the introduction of the speculum, or pressure made with the finger at certain points, must give rise to more or Traction is thus made through the connective tissue on the peritoneum and along some shortened line of adhesion But we are to be all the more careful when pain does exist under these circumstances, through fear of setting up a fresh attack of peritonitis The most important point that we have to consider is to ascertain, if possible, the modus oper and of the tampon, for only by the possession of this knowledge can we determine upon the fit subjects for its application Experience certainly teaches ing the tampon that by the use of hot-water vaginal injections contraction of the arteries is excited, and that these injections are most useful in active inflammation the same means we have ascertained that the tampon does positive harm when not indicated, acting as a source of irritation so long as any acute inflammation exists, it does not lessen circulation through the arteries, as their coats are not sufficiently compressible

We therefore can draw but one conclusion, and in doing so we reach the point that the tampon acts mechanically, by compressing the dilated veins and by lifting the uterus to its natural position in the pelvis, so that the circulation between the arteries and the veins may be equalized If the floor of the pelvis has been injured in childbirth, one or both agents may have to be employed to prepare the woman for the needed surgical operation And it is only by the proper execution of this operation that we can restore the fascia and connective tissue in the pelvis to a state of integrity, and thus indirectly give the neces-

sary support to the vessels

But we have a different condition to deal with in treating the effects of a local peritonitis As soon as the adhesions have been separated by the steady pressure of the tampon the pelvic tissues begin to And as the prolapse is corrected regain their tone by the use of the tampon, and the uterus is steadily maintained in its natural position, the smaller veins are able to regain their natural and tortuous course with the improved condition of the connective tissue So far in the treatment of a case the use of the tampon is most satisfactory, but as we advance the prog- is easy to tampon so that the uterus will be lifted with ress becomes slower We have at last reached the out making direct pressure The tampon should be point where the permanency of our previous success | placed so as to make as little direct pressure to the left in the treatment of the case must rest upon our being as possible along the course of the rectum. After the able to effect a radical change in the condition of the introduction of a sufficient amount of cotton we are to degenerated venous diverticula But it is just in this pass the index finger carefully over every portion to condition where I believe we gain the chief advan- be certain that it is uniformly placed and to smooth tage in the use of the vaginal tampon not, however, be misled by expecting too much, and is properly done it is possible, from the coherency of we must realize that we can only gain permanent good through use of the agent after a long and tedious application, which may extend over the course of months Moreover, the patient must be, as a rule, favorably situated in a hospital for receiving the treatment, and the operator is only able to do full justice efforts to miscarry The first is to keep the uterus, to the patient in proportion to his experience

I am unable to understand how anything is acthrough the long, steady, and uniform pressure which is maintained by the tampon when properly applied It is impossible to suppose that these degenerated vessels ever could regain their tone A certain amount of shrinkage doubtless takes place after they have been for a long time kept from being over-dis-But the continued pressure exerted by the tampon is but the application of a principle which has been long employed in general surgery. It is reasonable to suppose, therefore, that the contents of these vessels become gradually organized, more or less adhesive inflammation is excited by pressure, and eventually the tract throughout is obliterated

As to the material for and the method of introduc-The best material is the cleanest quality of cotton wool as sold in the shops and put up in rolls For the tampon I prepared a number of pieces of cotton of about the width and thickness of I then made a ball of each by turning four fingers the four corners or edges together, and while grasping these I thoroughly smeared the outer surface with Each ball was then of about the size of an vaseline English walnut, and kept its shape as it was packed loosely into a tin box for use It was found advisable to have these balls of cotton as nearly uniform as possible and of about the size that I have indicated

On beginning the operation it is sometimes necessary to place the patient on the knees and chest before the uterus can be replaced Then several balls are to be introduced and placed at a point where the uterus can be held by means of the finger while the patient is turning upon her back already stated my reasons for preferring this position in introducing the tampon One ball of cotton after another should be placed in the vagina and passed closely along the index finger of the other hand, which is engaged in pressing back the permeum and in holding up the uterus or that portion of the tam pon already introduced If one part of the vagina is more sensitive than another we must learn to "humor" it by making less direct pressure until tol erance becomes established When the sensitiveness is situated in the neighborhood of one of the broad ligaments we must pack the cotton on the opposite If the inflam side of the cervix to act as a crutch mation is chiefly about the utero-sacral ligaments, it We should down the entire surface When this "finishing off" the cotton and vaseline, to pack but a portion of the vagina It may be but the upper part, or to one side, and it is likely to remain in position

There are two practical points in the application which, if not carried out carefully, will cause all our throughout the whole course of treatment, as nearly as possible in its natural position and at the same plane in the pelvis The other is to place the fresh tampon without delay after the other has been re-I have been in the habit of renewing the tampon daily for the patients in my private hospital But if it could be kept deodorized, the longer it remained undisturbed the more thoroughly would both portions are to be removed of these indications be met in practice

The best instrument for removing the cotton is a piece of whalebone with a rough screw cut in the end, a simple device for the application of which we are indebted to the late Dr Sims This is easily passed alongside of the finger and twisted into one It is well to leave that part portion after another directly under the uterus until the last, so that the finger may be slipped beneath the cervix, at the proper moment, to hold it in place until the fresh tampon can be introduced To facilitate this, everything should be prepared beforehand It is very evident if the uterus is allowed to prolapse, that just in proportion as it does so the circulation must be disturbed, and that if there is any advantage to be gained from maintaining a steady and uniform pressone Therefore there should be no unnecessary delay in returning the tampon, as the blood begins again to rapidly dilate the vessels as soon as the pressure is removed

A serious drawback to the satisfactory progress to be gained by this mode of treatment is the recurrence of the menstrual period, when the use of the tampon has to be discontinued Just before the period is ex- most indefinitely duce one of the rubber rings which I have already the introduction of the finger between it and the vaginal wall at any point an inch in diameter, and so long as the patient remains in the recumbent position their broad surface offers a fair substitute for the tampon both in exerting a direct pressure upon the larger vessels and by taking up the slack in pelvic tissues As soon as the flow has ceased I have a large hot-water vaginal injection administered, and then apply the tampon as before in the continued treatment of the case -N Y Medical Journal, February 18, 1888

subject, says

The opinion most widely prevailing at the present of the astragalus flesh, and more especially to beef The results obbeef prepared in a certain and most excellent man- used ever we may think of the theories and methods of but a small portion having been absorbed

chopped finely, seasoned to taste, and made into little cakes, which are eaten raw or slightly browned on the gridiron It may be taken in the form of rare beefsteak broiled in its own fat, or as very rare roast beef Other methods of cooking are to be prohibited The meat is to be as juicy as possible, and fibrous

Very often one can be satisfied with the use of butcher's meat, raw or cooked as above Sometimes, however, whether from partial failure of digestive powers or other conditions necessitating reduction in bulk without loss of nutritive material, or suggesting conservation of the energy that would be expended in digestion, it becomes necessary to resort to special methods of preparation The meat powders prepared by various pharmacists, more especially for forced feeding, here render valuable aid By cutting boiled beef into fine pieces, drying by means of a water bath, and grinding in a coffee mill with the teeth set closely, an excellent meat powder may be made in the kitchen (Dujardin-Beaumetz)

The preparation from which Cohen has seen the ure, it must be, as nearly as possible, a continuous greatest benefit, and which he is in the habit of most frequently prescribing, is beef peptonoids from improvement in the process of manufacturing, rendering it more palatable, or from decrease in the fastidiousness of patients, there has not recently been the same difficulty in getting patients to persevere in the use of it that was experienced in former years

The methods of administration may be varied al-It may be added to soups and pected I remove the tampon and immediately intro- broths, to milk punch, egg-nogg, etc., taken in warm or cold water, or made into a paste with milk or referred to, and one of a sufficient size to admit of water and spread upon bread Beginning with a teaspoonful three or four times a day, the amount is These rings are about 34 of to be increased, as soon as the preferable method of administration is determined upon, to a tablespoonful It is preferably given among the suppleor more mentary articles of diet, between meals - Dietetic Gazette, January, 1888

POISONING FROM BORIC ACID, IN SURGICAL PRAC-TICE -DR SPENCER, of St Paul, reports the follow-A short time since a woman was admitted ing case to the City Hospital with syphilitic necrosis, and caries of the bones forming the ankle-joint October MEAT IN PHTHISIS - COHEN, in a paper on this 2, he removed by scooping, scraping, etc., parts of the lower ends of the tibia and fibula, and nearly all The sinuses in the soft parts time assigns the first rank as an aliment in phthisis to about the joints were scraped as clean as possible, the cavity was washed out with a weak bichloride tained by certain individuals, who devote themselves solution, and packed with large clystals of boric to the treatment of disease by an exclusive diet of acid, probably something over half an ounce being Although the wound was very foul smelling ner, conjoined with lavatory potations of hot water at the time of operation, it was left undressed for a to prepare the digestive canal for the reception and week and was then found nearly free from odor disposition of the aliment, cannot be ignored, what- Most of the acid was still undissolved in the cavity, the practitioners in question. Without confining washed out and dressed in the same way as before, themselves to beef, scientific physicians are justified and left for another week. During this time, fourin giving it the first rank. It should be taken at least teen days, her health, appetite, and general conditwice daily, three times if possible It may be eaten tion were good She then began to lose her appetite, raw, as it comes from the butcher, or it may be and in a short time had nausea and vomiting, which grew progressively worse, so that, finally, nothing could be retained by the stomach Lime water, counter-irritation, and cold to the epigastrium, morphia, ipecac, and all the various anti-emetics Her other symptoms were restwere used in vain lessness, insomnia, the little sleep she did get being very disturbed, almost constant hiccough, great weakness and emaciation, and a very marked cardiac Although her pulse was very weak, there was none of the compensating rapidity which generally occurs in heart failure She had a rather severe coryza, the conjunctive were very red and inflamed, there was marked inflammation of the fauces and pharyna, some bronchitis, and an acrid discharge Her tongue was red, from the anterior nares glazed, and cracked There was a very wellmarked papular crythema, the papules nearly coalescing over the face, neck, arms, and upper part of These symptoms came on gradually and grew worse for three days, at which time she was very weak, though she had taken considerable nour-The dressing was then changed, ishment by rectuin and the symptoms here noted began to disappear, although it was ten days before she was as well as before they began - Northwestern Lancet, January 15, 1888

TREATMENT OF SYPHILIS -In the issue of the Bulletin Gén de Therapeutique, of October 30, is a useful paper on the treatment of syphilis, by Prof As a representative of the more con-VERNEUIL servative of French surgeons, Verneuil speaks with authority on such topics The conclusions at which he arrives harmonize with the opinions most gener-He maintains the superiority of mercury As respects the diagnostic value of the two agentsiodides and mercury—he never decides the question of specific lesion or not, except from the results of a In three examples of old syphitrial of mercury loma of the testicle—cited for illustration—the iodide of potassium in massive doses failed to disperse the tumor, but mercurial treatment effected a cure in a few weeks, thus demonstrating the nature of the neoplasm

Professor Verneuil does not advocate the huge doses of iodide of potassium now in vogue-2 to 3 grams (30 to 45 grains) per day being his maximum-except in cases of rapidly destructive ulcerations of the nares, veil of the palate, and similar lesions, and even then in quantity not exceeding 75 He has never favored the or 96 grains per diem conjoint administration of mercury and iodides prefers to give mercury by itself, and associated with remedies to improve the general state of the patient He has occasionally made use of the combination of these remedies in slowly developing secondary or tertiary accidents when mercury does not act well, Under such circumor has not been given at all stances he prescribes in the simplest way 3/4 grain of protoiodide of mercury and 15 5 grains of potassium

10dide Mercurial frictions, although in some cases acting energetically, do not commend themselves to his When he has employed munction, he Lancet, January 14, 1888 judgment

has not dispensed with the internal administration of the protoiodide or some other mercurial, in small Nor has he practised the method of subcu doses taneous injection of mercurials, which often cures, apparently, in twenty to thirty days He holds that the most certain curative results are obtained by the slow saturation of the organism as effected by the stomachal administration rather than by sudden impression

For the local treatment of syphilitic ulcerations, mucous patches, etc , the early manifestations of the constitutional state, he employs nitrate of silver, or chloral solutions, topically, in conjunction with the use of mercury internally -American Journal of the Medical Sciences, January, 1888

TOBACCO AMBI YOPIA --- MR EDGAR A BROWNE, in an article on this subject, draws the following conclusions

The optic nerve resembles a sensory tract of the spinal cord, consists of two tracts, of which the central has a special affinity for tobacco, while other drugs, e g, quinine will leave it unaffected

Tobacco is the essential agent in causing an avial neuritis, which does not in ordinary cases tend to spread to the nerve-fibres coming from the pen pheral retina

3 As a rule patients apply in the early stage of neuritis, and complete recovery may be expected without any treatment except entire cessation of smoking

4 When recovery is established, moderate smok

ing is not injurious

5 Although it would be absurd to suppose to bacco is the only agent capable of causing avial neuritis, no other has yet been substantiated in a series of cases arising in strictly nor-smokers

6 Besides tobacco a special condition is required to precipitate an attack, alcohol, diabetes, excessive venery, starvation, mental shock, or distress, are the most common auxiliaries

7 In some persons a special tendency to degen eration (sclerosis or atrophy) exists hereditarily, to these tobacco is especially injurious - Liverpool Medico-Chirurg Journal, January, 1888

TYPHOID BACILLI AND BOILING WATER -In order to test the destructive power of boiling water on typhoid bacilli, DR VILCHUR, of St Petersburg, made a number of pure cultures in broth, keeping them in a thermostat for two days at a temperature of about 92° F, and then mixed them with known proportions of boiling water, immediately afterward The results showed sowing the mixtures in jelly that, when the volume of boiling water equalled that of the culture, the bacilli were partially but not When double the volume of boiling water was used, the bacilli were all killed wholly destroyed From experiments with typhoid stools, he found that all the bacilli, however numerous, were invariably destroyed by the addition of a volume of boiling water equal to four times that of the stool way he suggests it will be easy to disinfect with certainty all the dejections of typhoid patients -

THE

Journal of the American Medical Association PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBSCRIPTION PRICE, INCLUDING POSTAGE \$5 00 PER ANNUM, IN ADVANCE SINGLE COPIES TO CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order drawn to the order of the under algned When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

MEDICAL LEGISLATION AGAIN

In this Journal for January 28, 1838, we called the attention of our readers to the necessity, or at least the desirability, of more uniformity in the laws enacted for the regulation of medical education and practice in the several States, by citing some of the diversities at present existing and the inconveniences to which they must subject practitioners in moving from one State to another In alluding to the medical registration law of Pennsylvania, we carelessly and erroneously mentioned a State Board for the execution of the law, when the law provides no State Board, but requires the registration of practitioners to be made by the prothonotaries of the several counties An editorial in the Philadelphia Med ical Times, of February 15, 1888, properly reminded us of this error, and then proceeds to pervert the whole tenor of our article It calls our simple illustration of the working of that feature of the Pennsylvania law which requires all graduates from colleges outside of that State to have their qualification endorsed by the faculty of some medical college in that State, before they could be registered as legal practitioners, as uncomplimentary, and yet admits its entire correctness

It proceeds further to commend the law on the plea that the possession of a diploma from a legally established medical college, either in this or foreign the person actually had all the qualifications neces-

medical college in Pennsylvania The correctness of this plea few will be inclined to deny, but, unfortunately, the inhabitants of the world outside of Pennsylvania will be so incredulous or uncharitable as to suspect that even the faculties of the medical colleges in Pennsylvania may award the diploma to some of their own students who are not possessed of all the And if they should, how does qualifications desired the Pennsylvania law protect her own citizens from such? As we observed in our previous mention of this subject, the legislators of New York State have already returned the compliment by enacting a law that makes it necessary for graduates from medical colleges outside of that State (not excepting those in Pennsylvania) to apply to a medical college Faculty in New York for special endorsement before they can become legal practitioners in that State Now let Massachusetts enact a similar statute, and if any graduate in Pennsylvania, or New York, or elsewhere, wishes to practice in the old Bay State, let him get the proper endorsement in Boston the States in the Mississippi Valley will not be slow in adopting the fashion, and the usually large number of graduates from the colleges of New England, New York and Pennsylvania who wish to settle in the West and South must submit their credentials and qualifications to the examination and approval of a medical college faculty in whatever State they propose to practice

299

The specially ludicrous feature in this kind of legislation is the effort to protect the people of each State from the presumably unqualified graduates from the schools of other States, while they make no provision for protection from possible unqualified graduates from schools within their own boundaries, the practical result of which, would be to keep all the poorer medical students who barely succeed in graduating at the lower margin of the scale within the State where they graduate, through fear of failure to pass review by another college faculty elsewhere, while those most highly qualified, being well assured of their ability to pass review anywhere, would freely migrate from their own to other States or Territories wherever choice locations were to be found little less amusing is the assertion of the Medical Times that we evidently believe other examinations or safeguards than medical college graduation are not necessary to secure for the people a properly educated medical profession, when we have for fifty countries, could not be safely regarded as proof that years, on every suitable occasion, advocated the establishment of a properly constituted Board of Exsary for a safe practitioner of medicine, unless he ob- aminers in each State, independent of all colleges or tained a special endorsement by the faculty of some institutions for medical instruction, by whom all persons proposing to study medicine should be examined courage such infringement of the patient's rights by concerning their general education, and admit to registration as medical students only such as furnish full proof of good English education, including mathematics, physics, the natural sciences, and in addition the elements of the Latin language, and by whom all persons proposing to enter upon the practice of medicine in any of its departments within the State should be fully examined in all the branches of medicine, both scientific and practical, and grant licenses or admit to registration only those who are found lows on the relations of the profession to the public qualified, without any regard to college diplomas And we have repeatedly advocated the same in the columns of The Journal, as our editorial confrère might have learned by looking over its editorial columns even during the preceding two months

The medical legislation of North Carolina, Alabama, Virginia, and Minnesota, is already placed fairly on the proper basis, only needing some additional details, and we are hoping that the Committee appointed by the Section of State Medicine of the American Medical Association at the last annual meeting, will report such form of law as will receive the sanction of the medical profession generally, and will become the basis of the medical legislation in all the States, thereby securing substantial uniformity of laws regulating medical education and practice, instead of the present inefficient and too frequently contradictory enactments of the several States

THE RELATIONS OF THE MEDICAL PROFESSION TO THE PUBLIC

There seems to be a growing tendency on the part of the newspapers to gratify a morbid public curiosity and craving for harrowing and sickening details, however much individuals may suffer thereby, or however innocent the individual may be of having committed wrong or omitted right doing And with this tendency there is another, almost as vicious, of the newspaper's presuming on the ignorance of intelligent readers, and neglecting to take measures to In short, newspaper policy cure its own ignorance seems to be tending more and more to a reversal of the Golden Rule-which is just as good to-day as it was two thousand years ago-and one may sum it up as "Do unto others as you would not be done by "

medical profession to the public? So much physicians should see to it that when the public press newspaper notice may be much less prevalent in seeks to encroach upon the rights of their patients— Philadelphia than in some other localities, the hope and patients have rights—they should not aid or en- is to be indulged that it may eventually become en

violating confidences As the press has no right to pry into the personal maladies of a person and furnish them to the public, the physician, as a matter of justice to the patient, has no right to aid the press in any way in making unjustifiable disclosures

And there is an ethical aspect of the question concluding his annual address before the Philadelphia County Medical Society, January, 1888, the President, Dr J Solis-Cohen commented as fol

"It is to be deplored, on the score of professional ethics, that mention of some of our scientific work is occasionally noted unofficially in the public newspapers, despite the express interdiction in our By-Whether this prohibitory clause be deemed judicious or not, it is plainly the duty of all members to accede to its behests Those who disapprove of it should present their reasons for doing so in full meeting and should endeavor to have it rescinded They have neither the right to ignore it on the one hand, nor the right to disobey it on the other On several occasions when reporters of the daily press have been present at our meetings they have assured me that they were present on invitation of a member, that they had no desire to intrude, and had believed that their presence would be agreeable to This subject leads me to offer a few the Society remarks upon certain relations of the profession to While there is no reason to doubt that the public much of the individual editorial advertisement of subjects discussed or to be discussed at societies, or of operations performed or to be performed in public places or in private, is due to officiousness on the part of a student, a follower, an attendant or a pa tient, there is equally good reason to believe that most of it is courted, directly or indirectly, by the Of this fact I have been individual most interested amply assured by newspaper men who have been my own patients, and to whom I have put the ques I have been assured, further, that it tion direct could be taken for granted that little matter of per sonal medical importance ever gains access to the papers without the knowledge of those most infi On the other hand, it is equally mately concerned true that matters of some immediate momentary interest to the public do not always reach the news papers, even when passing through the mails in hun But what has this to do with the relations of the dreds of notices openly printed upon postal cards

"While it is gratifying to believe that this itch after

The disease at present is in tirely extinguished great measure a mere matter of taste-quite poor taste, according to the ethics of the Philadelphia County Medical Society

"One custom in which the ordinary conduct of the physicians of Philadelphia is to be commended, in their relations to the public, consists in their unwillingness to cater to gratifications of the morbid appetite of the newspaper public for tattle as to the nature of the diseases with which some of their distinguished patients may be afflicted, and as to the prospects of their death or survival Propriety indicates that such inquiries should be referred to the patient if he be in a responsible condition, or, if otherwise, to that member of the family upon whom the responsibility has devolved The confidential relations of a patient to his physician should remain undisturbed even when the patient is no longer competent to withdraw his confidence, and no communications presumptively disagreeable to him in his senses, should be furnished for press gossip without the consent of those who are most immediately in-The pleasure derived by an invalid from the daily perusal of his favorite newspaper is often exceedingly great, far greater than when, under the tuberculous animals Methods of preventing them press of affairs, he read chiefly headings and tele-He reads it much more thoroughly, sometimes even to the advertisements As he reads day by day, of what is going on in the great world outside, his little world of bed room life seems somewhat less constricted Let us avoid curtailing his gratification by acts of ours If his newspaper cannot be taken up without a dread of seeing some paragraph discussing the nature of his malady and the prospects of his early demise, this innocent source of enjoyment is poisoned for him rest content with a mutilated paper, the very gaps in which are repulsively suggestive, or he must consent to have it read to him, or give it up altogether and thus become deprived of taking interest in many things outside of his own illness It is hard enough for him to fear or to know that his malady is incurable, without having the fact forced upon his attention at some comparatively happy moment when it is out of his thoughts Harder still, perhaps, to steel himself into indifference

"It is unnecessary to mention examples must be familiar enough In some instances there has been abundant reason to believe that death has been hastened by thoughtless comments in newspapers Shall the individual always be sacrificed to the multitude? It has been stated that occasionally, when Evolution of local tuberculoses potentates or very wealthy individuals have been the tive of the bacilli of Koch

subjects of these items, special copies of newspapers have been printed for their use, in which the objectionable personal passages of the general edition have been replaced with other matter But there is little hope that the sores of the afflicted shall not be exposed to public gaze, unless their own physicians protect them by the charity of their reticence public maw is so rapacious, that the average newspaper man dares not deprive it of any tidbit, however unfit the food, and, worse than the cannibal who sometimes kills the sick man that his people may devour him, the editor sometimes delivers the sick man to his readers that they may devour him even while he is dying "

HUMAN AND ANIMAL TUBERCULOSIS

The announcement and programme of a Congress of Physicians and Veterinarians to be held in Paris on July 25-31, for the study of human and animal tuberculosis, have been received The Committee on organization has selected the following questions for discussion

- I The dangers of the use of meat and milk of
- The human races, animal species, organic media considered from the point of view of their aptitude to tuberculosis
- 3 The ways of introduction and propagation of the tuberculous virus in the economy lactic measures
- 4 The early diagnosis of tuberculosis in man and animals

In addition to these subjects the Committee desires to direct special attention to the following subjects

Heredity of tuberculosis in man and the different species of animals 2 The contagiosity between man and man, between animals, from animals to man, and vice versa 3 The different modes of evolution of experimental tuberculosis according to the quality and quantity of the virus inoculated 4 Difference in tuberculous affections in different species of animals 5 Methods of distinguishing the lesions caused by the bacillus of Koch, granulations, and inflammations due to different microbes (zooglea, bacteria of contagious pneumonia of swine, aspergilli, etc), to animal parasites, or to 6 Tuberculous lesions complicated foreign bodies by other microbial lesions 7 Mode of formation of giant cells and isolated tuberculous deposits 9 Agents destruc-10 Local and general

means capable of arresting the extension of experimental tuberculosis **I** I The value of surgical therapeutics in tuberculous affections

In addition to these subjects voluntary papers will be received provided they are confined to the sub-Foreign physicians and veteri ject of tuberculosis narians may become members of the Congress by writing to the Treasurer, M G Masson, 120, Boulevard Saint-Germain, enclosing \$2 00 The Secretary-General is Dr Petit, 11, Rue Monge, Paris

INJECTIONS OF ALBUMEN AND ALBUMINURIA

DR PAUL SNYFRS has recently completed a series of experiments undertaken for the purpose of controlling the experiments of Semmola on the pathogenesis of Bright's disease He injected into dogs white of egg diluted with a small quantity of distilled The operations were done by means of a water syringe of double the capacity of the ordinary Pravaz syringe The syringe was carefully disinfected before each experiment, and the quantity of albumen injected varied from 4 to 5 grams per kilogram of the ani-When this quantity is compared with mal's weight the amount of albumen excreted daily by the kidneys in the gravest forms of nephritis, it is seen that the quantity injected into the dogs was incomparably After the animals were greater than that excreted killed the kidneys were examined in the fresh state by congelation, and after the action of osmic acid, absolute alcohol, Muller's fluid, or boiling water Continuous injections during three, six, nine, and twenty-three days never produced glomerulitis certain points albuminous coagula were found, and a little diapedesis on the interior of the capsule no case was there any fatty degeneration of the These facts led Snyers to draw the folepithelium lowing conclusions

- I The albuminous (albuminuric) dyscrasia determined by the injection of egg-albumen is transitory, and ceases within twenty-four hours after the injec-The albumen found in the urine is only the tions It is a useless white of egg that has been injected substance, passes through the organism, and is eliminated naturally by the kidneys without producing any lesion
- 2 Histological examination of the kidneys shows no sign of any lesion of these organs, even after the injections have been carried on for thirty days
- 3 The fact that injections of white of egg cause an albuminuma that is absolutely transient, and withclusion injections of white of egg are incapable of is "U S Marine Hospital Service, New York, N Y"

producing either the lesions of nephritis, or a patho_ logical albuminuria

These experiments, recorded in the Bulletin de l' Academie royale de Médecine de Belgique, absolutely contradict the experiments and conclusions of Semmola, with regard to the causation of a clinical picture of Bright's disease by subcutaneous injections of white of egg

STHOPHANTHUS IN METRORRHAGIA -DR V POU I ET, of Plancher-les-Mines, calls attention in the Gazette de Gynecologie, of February 13, 1888, to the use of strophanthus in metrorrhagia of the menopause and that of very fleshy women during the age of fecund-As is well-known, ergot is very useful in the first class of cases, but has little or no effect in the But Poulet has used strophanthus in both second classes of cases for almost three years used the drug in substance, 5 centig of the recently powdered seed with a sufficient quantity of honey to Two pills are taken the first day, make one pill three the second, and four a day after that, if necessary Poulet claims, also, that he has had exceptionally good results from the use of strophanthus in typhoid fever, and will soon publish his cases

"THE MEDICAL JUDISPRUDENCE OF INEBRIETY," a volume of 200 pages, is announced as soon to appear from the press of the Medico-Legal Journal, No 57 Broadway, New York, N Y It is to contain the large number of papers presented and discussed by members of the New York Medico-Legal Society, and others, touching the relations of jurisprudence The price of the volume in cloth is and inebriety to be 60 cts, and in paper, 30 cts, orders for which may be addressed to the Medico Legal Journal, New York

TRANSACTIONS OF THE NINTH INTERNATIONAL MEDICAL CONGRESS —We have reliable information that the publication of the Transactions of the recent Medical Congress at Washington, is progressing satisfactorily, with the strong probability that at least three volumes will be ready for delivery early in May The members of the Committee of Publica tion are pushing the work as vigorously as possible

THE ADDRESS OF S T ARMSTRONG, M D, U S Marine Hospital Service, Secretary of the Section of State Medicine, of the American Medical Association,

SOCIETY PROCEEDINGS.

GYNÆCOLOGICAL SOCIETY OF BOSTON

Stated Meeting, November 10, 1887

WM G WHEELER, MD, IN THE CHAIR

A communication from the President, Dr H M FIELD, was read, in which he resigned his office because his own health and that of members of his family demanded that he should spend the coming winter in a milder climate On motion of Dr L F Warner it was voted that the resignation of the President, Dr H M Field, be accepted, and that the thanks of the Society be given him for his efficient and valuable services in its behalf

PATHOLOGICAL SPECIMENS

DR E C Keller exhibited to the Society the two following specimens which had been removed by her from patients at the New England Hospital

Removal of Ovaries and Tubes for Psosalpinx - Patient, æt 44, had suffered excessive pain since last June and temperature had been high, excessive abdominal tenderness On operation pus was found in the tubes and ovaries Pus had also escaped into the abdominal cavity A fibroid was found on side of uterus opposite to pyosalpinx Re-

Multilocular Fibroid -Patient, æt 45, Case 2 had flooded for two years, recently it had recurred every ten days and had been excessive, patient was blanched and life had become a burden There was A multilocular fibroid was removed and no pain patient made a good recovery

DR A L Norris presented a specimen of

CANCER OF THE STOMACH,

which was especially interesting from its history Patient, æt 76, forty years ago thought that she swallowed a water limpet while drinking water her stomach, and she has suffered much of many doctors in her efforts to get rid of it Dr Norris saw her but recently and made the diagnosis of cancer of the stomach On autopsy such was proved to be the case

DR H O MARCY then read a report of

A YEAR'S EXPERIENCE IN PRIVATE HOSPITAL PRACTICE

Whole number of operations, 81, deaths, 1 toration of the perineum, 11, anterior colporrhaphy, 3, urethral caruncule, 2, curetting endometrium for various causes, 25, operations for the repair of the cerviv uteri, 9, cancer of the uterus, 4, removal of cancer of the breast, 5, laparotomies, 7, Alexander's operation, 1, hernia-radical operation, 2, hemorrhoids, 3, miscellaneous, 9

been in his private hospital a single case of septiceeach important operation, and the room closed for the facts in regard to these growths

spray is not used, as a rule, during operation Surgeon and assistants must be specially clothed, and cleansed by scrubbing with mercuric bichloride and soap even to hair and beard Dr Marcy's method of restoration of the floor of the pelvis in cases of ruptured perineum is somewhat peculiar The portion of the levator ani anterior to the rectum is the part of the muscular structure which has been ruptured, and it is the restoration of the separated, retracted portions which he holds as important to This is best effected by freeing the posterior half of the vaginal muscle from its attachment is easily done by making the parts tense with two fingers in the rectum, splitting the tissues, in considerable degree cicatricial, until the loose connective tissue septum between vagina and rectum is reached The separation is carried to the upper border of the prolapsed vaginal wall and is held forward by an assistant, while the floor of the pelvis is restored by This is best effected by tendon continuous suture the use of a rather large, fully curved needle, the Hagadorn pattern preferred, burying the suture deeply in order to bring together the retracted mus-The detached vaginal portion is carefully adjusted to restore the vaginal opening, and the edges coapted by a fine tendon continuous suture cases of extensive injury, the double pin is used so as to hold firmly at rest the tissues during repair Where there is complete rupture the same operation is advised, after the dissection closing with great care the rectal and then the vaginal side of the triangle

The fatal case was from rupture of a papillomatous cyst of the left broad ligament

DR S N NELSON exhibited two specimens from two of the cases referred to by Dr Marcy

Case I Cancerous Uterus removed by Hysterectomy -This uterus had been repeatedly curetted for the relief of the flooding, until nothing but a shell of the original uterus was left Hysterectomy was decided upon and was done by Dr A Martin, of Berlin, during his recent visit to this city. Sepsis superhas always maintained that the animal remained in vened, but a satisfactory recovery ensued, and the patient was discharged at sixth week

Case 2 Ovarian Tumor consisting of a Single Cist—The principal interest attached to this case was the ectasic type of the vessels of the broad ligament supplying the tumor To guard against hæmorrhage from these vessels Dr Marcy used a double line of sutures with the shoemaker's stitch

DR E W Cushing said that the cases usually called adenoma of the uterus had interested him the In the case reported upon which hysterectomy was done for cancer he had curetted the uterus thoroughly in 1885 for a growth that was then called by competent men a simple adenoma He had at that time prophesied that it would evenually prove to be cancer, and such was the case These cases are constantly appearing which, according to present author-In the entire list of the year's work there has not lines, are simply glandular, but which are really practically malignant The question naturally arises, mia. The walls and floor of his surgery are washed where do the simple glandular changes end and canwith I 1,000 mercuric bichloride solution before cer begin? Schreeder's teachings do not represent Future study an hour subject to the spray of carbolic acid. The upon this point will lead to an earlier recognition of the malignant tendency of these growths and the necessity of radical measures. When an adenoma appears after the climacteric and shows a tendency to bleed freely it is cancer, and hysterectomy should be done.

In cases of repair of the perineum Dr Cushing had been led by experience to depend less upon the pins than upon deep sutures. These sutures should be of catgut, and if they are thoroughly antiseptic they will become organized and cause no trouble.

The question as to what should be done with the flap of vaginal mucous membrane has never been definitely settled. If it is simply left it is likely to become ædematous and tender. Dr Cushing's practice has been to sew this flap to the floor of the vagina. If the suturing is carefully done with fine sutures, no trouble will follow. This method will supersede all others, because in this way all the mucous membrane is saved. This consideration is an important one when we consider that the patient may become pregnant and need all possible material to secure proper dilatation of the vagina.

MONTH OF PREGNANCY

As the opportunity is not often afforded to examine the uterus at an advanced period of pregnancy and as this particular specimen presents several well marked and interesting features. I felt that it would be of interest to place it before the Society. The uterus was removed twenty-four hours after death, in asmuch as I was present at that hour I wished to do so immediately but could not secure the consent of the family. I shall very briefly call attention to the several conditions noticed. The outer surface of the uterus is studded with syphilitic nodes.

DR A P CLARKE said that he had seen Dr Cushing operate for repair of the perineum, and considered it wonderful to save so much tissue

DR E C KELLER asked Dr Marcy in regard to his experience in dilating and curetting the uterus

for relief of dysmenorrhæa

DR MARCY, in closing the discussion, said that he regarded the treatment of endometritis by dilatation and curetting as a gain. If the uterus and cervix are surgically clean the cervix can be forcibly dilated The parts are first thoroughly cleansed by the use of a 1 2,000 hot bichloride solution, and then the cervix is rapidly dilated to a No 25 F Curetting This will admit the curette changes the vascularization of the uterus, in this way it changes the nutrition of the tissues and re-In regard to operations for lieves dysmenorrhœa repair of the perineum Dr Marcy said that this operation was simple, both in its principles and technique, but that as yet there was no settled conviction among The leaders the profession as to the best method of the profession in New York pay no attention to reuniting the muscular fibres of the transversalis perinei, and thus overlook an essential feature of the When a tear of the permeum of any operation magnitude occurs the fibres of this muscle are severed and are retracted to a greater or less extent As long as these muscular bands are left ununited they tend to draw back the posterior vaginal wall and In the operation the muto increase the difficulty cous membrane of the posterior vaginal wall should be thoroughly dissected up and the ends of the transversalis perinei sought for and united by catgut su-Only by doing this can the best results be tures This point in regard to uniting the muscle was overlooked by even Dr Jenks, who originated the method of dissecting up the posterior vaginal He did this only as a protecmucous membrane tion for the damaged parts below Dr Marcy denied that the transversalis perinei is ever histologically absent, as is claimed by some who deny the necessity of reuniting the fibres of that muscle

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, December 8, 1887
THE PRESIDENT, T M DRYSDALE, MD, IN THE
CHAIR

(Concluded from page 212)

DR HAMIIL exhibited a

UTFRUS RLMOVED FROM A WOMAN IN THE LAST MONTH OF PREGNANCY

As the opportunity is not often afforded to exam and as this particular specimen presents several well marked and interesting features I felt that it would be of interest to place it before the Society The uterus was removed twenty-four hours after death, in asmuch as I was present at that hour I wished to do so immediately but could not secure the consent of I shall very briefly call attention to the several conditions noticed The outer surface of the uterus is studded with syphilitic nodes The woman had contracted syphilis early in her married life and manifested other marked symptoms of the disease There is also a small cyst of the broad ligament The specimen presents quite markedly the contrac tion ring or ring of Bandl I give both designations advisedly inasmuch as it is not definitely determined whether this ring represents the internal os as Bandl claims, or whether it marks the boundary between the upper and lower uterine segment as Schræder be lieved According to the investigation of McDonald, Muller, Sanger and Lusk this condition does not always exist In three autopsies made by Lusk he failed to find any trace of Bandl's ring Schræder in a frozen specimen found this ring very distinctly but claimed that it was the dividing line between the Bandl holds the upper and lower uterine segment contraction ring of Schreder to be the true internal os and consequently one would expect to find below this ring cervical mucous membrane, whereas, the portion between Bandl's and Muller's ring is covered Bandl explains this by his three hy potheses, I The deciduous membrane is crowded by deciduæ down into the cervix by the weight of the presenting part 2 In primaparas the advancing head strips off the mucous membrane which is replaced by deciduæ That the cervical mucous membrane is transformed into decidual membrane during pregnancy

Another interesting feature that the specimen dem onstrates beautifully, is that condition pointed out by Leopold and Lusk, as seen in their Cæsarean sections, viz the delicate filamentous bands running from the chorion to the deciduæ, which are the atrophied villi of the chorion. The attachment of the placenta is to the posterior wall of the uterus

DR HIRST had seen the frozen section made by Schræder, in 1884, and it was most interesting show ing distinctly the so-called ring of Bandl He did not believe in any one of Bandl's three hypotheses to account for decidual membrane in a place where according to Bandl's theory, cervical mucous membrane should be found The extraordinary diversity in the explanation advanced by Bandl shows plainly enough

the insufficient ground upon which his theory rests atomical facts upon the living subject He had looked for Bandl's ring and had never been able to find that it existed. He is fond of turning in badly presenting more fibrous portion above the true internal os children and has had his hand in the uterus many less for some moments, the compression was always uniform and from all directions He has yet to find any constriction in the region of the so-called Bandl's ring alone He has in several cases observed hourglass contractions, but this was due to continued pressure on one side of the uterus, and consequent loss of contractility of that portion He does not believe that hour-glass contraction ever occurs in uncomplicated labor

Dr Parish remarked that in a Cæsarean section performed by Dr Foster, of Maine, the operator had observed a circular contraction This went to prove Cæsarean section performed by himself no such concircular contraction in a third case operated on by

Dr Allis and himself

DR GITHENS stated that in discussions before the Society in October, 1879, in December, 1879, and in October, 1880, upon the subject of "Hour-glass Contractions of the Uterus," Dr Albert H Smith, Dr R G Curtin and Dr W H Parish had reported instances of prolonged and forcible contractions of a ring of muscular fibre in the uterus above the internal os, the lower and upper segments of the uterus remaining flaccid In Dr Curtin's case Cæsarian section was being performed, the uterus of contraction was seen as well as felt In the other case a placenta or twin fœius was retained in the upper segment of the uterus May not this ring of muscular fibre so contracting be identical with that described by Bandl? In the case reported by A H Smith, the condition lasted for two hours and was relieved by hot-water intra-uterine injection doctor reported the point of contraction as being at up we may make some allowance and consider that it occupied a position near that described by Bandl as the location of the contraction band

child was removed the patient began to show signs of internal hæmorrhage The uterus was examined and found to be much distended An attempt was made to pass the hand in but it was done only with difficulty as there was a powerful contraction in the The body was found distended and lower segment very flaccid, and filled with blood He thought that this case proved that a contraction could occur in

the lower segment

DR HIRST quite agreed with Dr Price in thinking that these cases always arose from pressure He had

preceding remarks, to contraction of the circular DR M PRICE firmly believed in hunting for an-|muscular fibres, but was merely the sharply defined boundary between the upper, thicker and more muscular portion of the uterus and the lower, thinner,

DR HAMILL observed that the patient had formerly He has had it so compressed that it was use- suffered from Graves' disease but had no active symptoms at the time of death. She had died of heart

failure

DR HAMILL presented, also,

A FOUR WEEKS' OVUM ENTIRE WITH THE DECIDUÆ,

He presented this specimen for a two-fold reason 1 On account of its comparative rarity elicit from the members of the Society their views on the after treatment of abortion The expulsion of the deciduæ vera is not as a rule thrown off with the ovum entirely Durhssen says, "from a personal experience with more than 150 cases of abortion in the that such a thing could occur In two cases of service of the Charity of Berlin that the retention of portions of the deciduæ vera is not the exception traction had existed, and likewise there was no such but the rule," and Tarnier says "that ordinarily the uterine deciduæ remains adherent to the uterus" Whether it is safer to leave this in the uterus and allow Nature to throw it off or to remove it at once is the particular point I should like to hear the members For my own part I feel sure that it should be immediately removed As to the manner I shall say nothing

DR HIRST said that when the deciduæ vera is retained as is the rule in early abortions, one of two things happened, the mass either putrified and thus became a source of septic infection, or it became greatly thickened and remained as a foreign body, had not been emptied of the contents and the ring exciting frequent hæmorrhage or constant leucorrheea He always cleaned away any debris left in the uterus

after abortion

DR GOODELL agreed fully with Dr Hirst as to the propriety of removing the retained fragments of the placenta or the membranes, but he had a word to say about the manner of their removal He deemed The the much-vaunted curette, whether sharp or blunt, a very inferior instrument, especially so whenever the the internal os but as he was opposed to the idea of fragments had been retained for several weeks. Not there being any such thing as a contracting ring higher only did the curette bruise and injure the unimplicated portion of the womb, but it tended to glide over the fragment, merely scraping the surface Sometimes, indeed, it would hook up one end of the DR R STEWART had seen a case in which after the fragment and after causing a great and needless flow of blood, would slip off So often had he been disappointed with it, nay even alarmed by the great loss of blood, that he now used either a small fenestrated polypus forceps, when the os was dilated enough to admit it, or a slender handled catch-forceps these instruments the fragment was invariably seized and removed by a twisting movement, while the womb itself sustained no injury whatever It was in fact safer to use these instruments in the womb than to eatch a stone in the bladder with the lithotrite

DR PARISH had seen a number of mistakes made seen good examples of Schreder's contraction ring with the curette. He had been called to a case and in which the ring marked the dividing line between found a woman who had been bleeding for four or the upper and lower segments of the uterus, and was five months Her former attendant had curetted and not at all due, as might be inferred from some of the pronounced the womb empty He and his colleague

dilated and removed a body as large as his two fin- to the abdominal opening, making an artificial anus gers In another case the uterus was curetted by the Dr Agnewhad seen the case and had recommended attending physician and pronounced empty Within immediate operation The woman was a patient of twenty-four hours the patient aborted well illustrate how one may be deceived as to when that Mr Tait had first advised the prehminary punc the uterus is empty when relying on the curette his own practice, after three months if there is no retention he introduces his finger and delivers everything He thinks with Dr Goodell, that something more reliable than the curette must be used to enable one to say that the uterus is empty after abortions in doubtful cases

DR LONGAKER does not interfere before the third month at all unless the patient has decided signs of retention, such as hæmorrhage, patulous os, etc, otherwise it is as a rule safe to conclude that everything has come away During the third, fourth and fifth months retention is very frequent. He thought it surprising what a small portion of placenta would give serious trouble, even small shreds will keep up a very serious hæmorrhage He always removes anything which has been retained and uses the finger and very frequently anæsthetizes the patient

DR R STEWART asked the members of the Society in what proportion of cases they had to interfere He has never used the curette for this purpose and has never failed to remove with forceps of proper The hæmorrhage generally ceased in from twelve to fifteen hours, if not he investigates and usually finds some debris left behind, but is convinced that if there has been no improper interference at the time of the abortion, such cases are exceedingly rare He agrees with Dr Longaker as to the amount of trouble kept up by small pieces of membrane, etc

DR HAMILL also presented

A FŒIUS SHOWING INTRA-UTERINE RACHITIS

This specimen presents a number of anomalies, probably the one most rare is the condition of intrauterine rachitis, you will note the marked rachitis condition of both femurs So far as I am able to find 53 cases having been collected by Schorlan and Graefe This condition of the bones in rachitis may be simulated by the arrest of bony development in those cases of fœtid cretinism occasionally met with The absence of the three fingers and corresponding metacarpal bones would, following the classification of Geoffrey St Halaire, place this among the Hemiteratic class and the subdivision of that class known as Anomalies by Numerical Diminution This form of monstrosity is not met with very The absence of the fibulæ renders the frequently specimen still more rare

DR J PRICE exhibited

A PIECE OF THE LARGE INTESTINE

removed that day by Dr Charles B Penrose patient, a woman, had not had a passage of the bowels reled Sharp's pistol, 30 calibre She had the muzzle for twenty eight days side of uterus and posterior The intestine was hand it slipped from her hold and fired the cartridge, The gut was then resected, a piece twelve inches long removed. The two ends of the gut were then united lobe of the liver, entered the upper third of the kid lobe of the liver, entered the upper third of the liver the liver the lobe of the liver the li in half their circumference and the other half stitched ney, and passing through lodged in the deep mus-

These cases | Dr Bernardy's She is now doing well He believed In ture to relieve the distension in conditions that can not be dealt with by resection He had some letters from Dr McMurtry, of Danville, Ky, who had been called 45 miles into the country to see a physician 26 years old On opening the abdomen he found two perforating ulcers of the cæcum with local pen tonitis He had trimmed the edges of the ulcers and closed with Lembert sutures, irrigation and drainage On the fourth day pulse 92, temperature 99, and patient had complete evacuation of bowels

DR PRICE also exhibited a

PELVIC-BOUND FIBROID

Woman, 37 years old Small Tumor on anterior face of pelvis bound fibroid could almost be picked up through the abdominal walls The R tube con tained blood and the ovary was bound down by ad The R tube and ovary were then tied off, but the L tube and ovary were so imbedded in a mass of large venous sinuses that it would have been dangerous to have interfered with the ovary The tube was removed A clamp was passed around the tumor which had been lifted out of the abdomen and The clamp came off on the the mass was removed Temperature was never above seventeenth day 100°, pulse above 65 In connection with this case he remarked that tubal and ovarian trouble compli cating fibroids was very common Dr Keith had found all the tubes diseased in about all his first 38 cases of hysterectomy In 9 cases he had attempted to remove them but had failed, and finished by hysterectomy He was surprised to find Dr Keith con demning the operation and thought that his statistics explained the matter His mortality in private practice was less than 4 per cent, and in hospital practice more than 15 per cent

PHILADELPHIA COUNTY MEDICAL SOCIETY

Stated Meeting, February 8, 1888 THE PRESIDENT, J SOLIS-COHEN, MD, IN THE CHAIR

DR MORDECAI PRICE read a paper on

A CASE OF NEPHRECTOMY FOR GUNSHOT WOUND

Maggie McG., of Avondale, Chester County, Pa, aged 14 years, white, pale, anæmic girl, was acci dentally shot on Wednesday, Dec 21, 1887, at 9 o'clock in the morning, while handling a four bar of the pistol turned toward the right side, while at The constriction was easily found on the right tempting to raise the lock with the thumb of her left which entered her body at the junction of the ninth cles of the back near the spine When we first saw her-twenty-four hours after the accident-her condition was an exceedingly alarming one, pulse 150, temperature 103° She had passed, soon after the accident, a large quantity of blood from the bladder But at the time of our seeing her she was not passing blood from the bladder, showing that if there was still hemorrhage it was into the peritoneal cavity, and also that the bladder was not wounded, for the urine was normal

Symptoms of peritonitis were well marked, abdomen considerably distended We had no difficulty in coming to a conclusion as to what was best to be Dr Charles Penrose and myself at once advised the removal of the kidney This was concurred in by Drs Hudder and Ewing, the attending physi-The patient was etherized and opened the abdomen, the wound of the liver was examined, both entrance and exit No hæmorrhage was found labors coming from it enlarged, and the blood removed from the region of dered during the operation the right kidney, when it was plainly seen that the inches hæmorrhage was from that organ The kidney was large enough for a finger to enter I then made a is better than Dr Price states kidney from its bed pushed back or inward toward the spine, and the is assured the vessels of the bowel were not disturbed ligaturing of the pedicle was exceedingly difficult, Dr Penrose having to tie the ligature the full length were applied, one through the pedicle tying it in halves, the other, a large, heavy ligature in one knot, then the kidney was cut away and the ligature tighture in it Rochelle salts was used, followed by two bowels, which gave great relief Patient did uninterruptedly well, with temperature not over 102° up to the time (eighth day) of the removal of the glass drainage tube, when rubber drainage was substituted and was left too long, producing quite a rise of temperature and fetid pus at the bottom of the tube, which was at once relieved by the attending physicians removing the tube and cleaning drainage track

On January 4 was telegraphed for, patient's temperature having been up to 103° the previous night Abscess was suspected either in the liver or the muscles of the back

ing, her attending physicians, in consultation, and found no positive indication of abscess—the girl being in a moderately good condition at the time. with a slight tendency to diarrhœa—temperature 100 4°, pulse 100 She continued to do well until January 11, when Dr Ewing wrote me "Some new trouble seems to be developing in our patient, her temperature is 103 2°, her liver is enlarged and tender, complains of pains in left side and shoulder " On the 12th there was quite a gush of pus and bile from the drainage tube opening-about two ounces. this at once relieved her of high temperature and She has had many changes in the last quick pulse three weeks, with slight discharge of bile and pus from the drainage tube, but has constantly, but very slowly improved Her physicians have given her every attention, and to them I am greatly indebted large quantity of clotted blood was removed from for the care they have given her, nothing but their interest in the case could compensate them for their For the result in this case I am greatly in-The abdominal incision was then debted to Dr Charles Penrose, for assistance ren-Length of incision six Kidney removed for hæmorrhage

DR EWING, of West Grove, said I have nothexamined and found to have a hole in its upper third, ing to add, except that the condition of the patient To-day there was button-hole opening through the peritoneum with only a drachm of pus discharged There is refreshscissors, introduced finger and enlarged the opening ing sleep, temperature is normal in the mornings, by tearing, and without much difficulty nucleated the though there is a slight evening rise, appetite is The ascending colon was good, the bowels are regular I feel that recovery This child was on the verge of death opening in the peritoneum, through which the kid- when the operation was done-the pulse was 150, ney was removed, was made in such a manner that temperature 103°, the extremities were cold, body The covered with clammy perspiration Improvement was manifest at once I am personally much indebted to Drs Price and Penrose for this operation, and I attribute its success to the neatness and dispatch with which everything was done, exhibiting a

high order of skill

Dr J B Roberts said The case speaks for itened before making the second knot. The stump self. While I cannot speak from experience, it has of the pedicle, or button, as it is called, to keep the occurred to me, and the same suggestion has been ligature from slipping, had a portion of kidney struct- made by others, that the difficulty of tying the stump There was complete irrigation A glass so far down and behind the peritoneum might be drainage tube was left in the kidney wound and the lessened by getting the kidney enucleated and then abdomen closed The patient rallied nicely from the twisting it so as to apply torsion to all the renal vesether, and, on the morning of the second day, Ep- sels, veins as well as arteries Afterward the ligasom salts was given in large and repeated doses, but ture might be applied with more ease, and this could not be retained On the morning of the third whether abdominal or lumbar incision be made, day a second attempt was made to have her bowels though in the absence of experience I judge that it would be easier to do this with a lumbar incision or three evacuations and passage of flatus by the I presume that there was no intestinal wound in this case, no mention having been made of any

In connection with the operation by lumbar incision I might refer to an error of my own which illustrates the mistakes our lack of familiarity with operations in this region may lead us into The operation was undertaken for a supposed stone in the kidney, but as no stone was found, it resolved itself into an exploratory incision and acupuncture of the kidney The ordinary lumbar incision had been made with care, and I had come upon the kidney with ease It was suggested that I should enlarge the wound up-I met Dr Hudders and Dr Ew- ward and explore the upper end A few muscular

fibres stretched across the upper angle of the wound, and these I divided by a small cut, when a rush of lumbar incision, which exposed the kidney closely air into the pleural cavity informed me that I had cut a small hole in the diaphragm The accident did the liver and to the iliac vessels. It was distended no harm, it was easily remedied with a few sutures, and the dyspnoea that persisted for a few days was moval attributed by the patient to the tightness of the abdominal bandage I was not sufficiently familiar with operations in this region to realize to what extent the posterior attachment of the diaphragm to the vertebræ dips down here, especially when I saw, as I did, the main mass of the diaphragm bulging down as a great sheet in front of the point where I made the additional incision

Hon does Dr Price ac-THE PRESIDENT said count for the bile?

DR PRICE said I cannot say where the bile comes from, except the liver The wound in the should be divided, thus avoiding the danger of gan liver is about two inches from the gall-bladder ball took a diagonal course and came out at the cess is given to the adhesions, especially those to the margin of the liver, and then entered the kidney did not know what the effect of twisting the pedicle I could bring the edge of the kidney would be within an inch of the wound I consider the abdominal incision the proper one. In this case there were several considerations in its favor rhage had already taken place into the peritoneal cavity, it gave us the chance to examine for wounds We found only wounds of the liver and intestines of the liver and kidney The liver was not bleeding, and we had only the kidney to deal with view of the discharge of pus from the liver, I now believe that it would have been better to insert into the track of the bullet in the liver a small glass drainage tube—this of Bantock's, which is of about the same diameter as the ball—and drained it as has been stated to me by Dr Wood, there has been no case of recovery from bullet-wound of the liver, we are not going to make the prognosis any worse by draining, and I think we might make it better.

Dr Frank Woodbury read a paper on A CASE OF NEPHRECTOMY FOR PYONEPHROSIS

In connection with the case reported this evening, I will briefly relate the notes of a case of nephrectomy performed for me by Drs Deaver and Agnew,

last year, at the German Hospistal

The woman first came to me in the spring of 1886, for vesical irritation, with bloody urine She had had several such attacks following exposure to cold and wet some two years previously In September of the same year there was another attack The urine contained pus, but no blood I washed the bladder with boric acid and alkalies, and subsequently with a weak solution of nitrate of silver The pus continued, epithelial tube-casts appeared, and a tumor slowly developed in the right side Dr Deaver saw the case in consultation and concurred in the diagnosis of pyonephrosis of right side consecutive to inflammation of the bladder Dr Agnew saw the case on December 25, and agreed in recommending opera-On January 10, 1887, nephrectomy was carefully and skilfully done by Drs Deaver and Agnew Death occurred five days later, from exhaustion.

DR Deaver said The steps of the operation were adherent to parts, especially to the under surface of with pus, six ounces being evacuated prior to its re-The mass was very large, and in delivering without wounding the peritoneum required great care I now regret that we extirpated, as I believe it would have been better surgery to incise the kidney, wash out the abscess cavity, insert a drainage tube, and to dress it antiseptically as in nephro-lithotomy

Much difficulty was experienced in ligating the pedicle, as in Dr Price's case I believe the abdom inal incision to be preferable in dealing with greatly enlarged kidneys In performing the abdominal operation, the meso-colon descending, instead of the internal meso-colon, carries all the blood-vessels, Delivery is easier, and better ac-The grene of the gut I iliac vessels

DR J B ROBERTS said The case of Dr Wood bury suggests some studies I made and reported to the American Surgical Association a few years ago, Something can be gained in the way of diagnosis in the early stages of peri-nephritic abscess and other lesions in this region by the study of certain trains of symptoms, pointing to the localization of the dis-Inflammatory affections about the upper end of the kidney, for example, will often show on care ful examination a limited pleuritis, when the lower part is involved there is apt to be spasm of the psoas muscle with flexion of the thigh, in the middle part pressure on the renal vein and other vessels may cause an otherwise inexplicable albuminuria

DR C B PENROSE presented a specimen of

DERMOID CYST OF THE OVARY,

which he had removed two days ago also had a uterus filled with many subperitoneal and interstitial fibroids, and a large blood cyst of the other ovary

DR PENROSE reported a case of

OBSTRUCTION OF THE BOWEL BY CANCEROUS MASS, OPERATION, WITH FORMATION OF ARTIFI-

CIAL ANUS

The operation was performed seven days ago There had been complete obstruction of the bowel. for twenty-eight days prior to operation vomiting occurred two days before operation time of operation there was immense abdominal distension, a temperature of 101°, and a pulse of 150 An abdominal incision four inches in length was made, revealing complete occlusion of the descending colon by a cancerous mass twelve inches long, in volving also the meso-colon

Resection was made of the gut and meso-colon, The two ends of and all indurated tissues removed the divided gut were brought together laterally and united to each other, and the long axis of the ab dominal incision, with continued suture, so as to A bucketful of fluid feces make an artificial anus was discharged immediately after the operation Relief was immediate, quiet sleep lasted for thirty-six

is clean, appetite good, and the patient doing remarkably well

Stated Meeting, February 22, 1888 W W KEEN, MD, IN THE CHAIR DR W W KEEN, read a paper on

A CASE OF MACEWEN'S OPERATION FOR THE RAD-ICAL CURE OF HERNIA, FOLLOWED BY A SPEEDY RETURN OF THE HERNIA

I think it important to report failures as well as Macewen's operation, also, has been so generally successful that it is the more important to report the failure of this case as the immediate result of the operation seemed to promise a cure, but, as you will see, the hernia has quickly reappeared For the notes of the case I am indebted to Dr Lambach, the Surgical Resident

The patient is a man 32 years of age, a fresco painter, but for some time at work dredging oysters When 17 years old he first noticed a right oblique inguinal hernia, for which he wore a truss for a year and then laid it aside The hernia remained cured A year ago, while at work for thirteen years dredging for oysters, the hernia returned, and descended into the upper scrotum He entered St Mary's Hospital January 6, 1888, on account of the distress and inability to pursue his occupation operation was done on the 13th, on the fifth day I pus at any time fifteenth day, his temperature rising to 103°, but as there was no evidence of suppuration, as it yielded promptly to quinine and arsenic, and as his occupation had exposed him to miasmatic infection, we were justified in attributing this to malaria He was kept in bed for twenty-nine days-ie, until Februhim yesterday, (February 21), I found the hernia had returned, with, however, one gain-at the time of the operation the external ring was very large, rethe point of the index finger Moreover, he is exceedingly comfortable, so much so that I doubt if I can persuade him to undergo another operation

An incision was made over the site of the hernia to its lowest point in the scrotum. With the blunt end of the scissors and the finger, the sac was then dissected from the surrounding parts, care being taken to leave no attachment to the spermatic cord The index finger then was passed within the abdominch around the circumference of the internal ring A moderately stout ligature of chromicized catgut

To-day the abdomen is flat, the pulse is 80 | Wilson's curved trachelorrhaphy needle, was then to 90, temperature 99°, there is no pain, the tongue passed through the abdominal wall from within outward at a point a half inch above and external to the internal ring, the skin being drawn upward and outward so as to allow the stitch to emerge through the abdominal muscular wall, but not through the skin Then traction was made on this stitch, thus puckering up the sac, which latter was drawn through the ring and rested against the inner surface of the abdominal wall to become adherent there, closing the hermal opening by a firm pad The stitch was then secured in place The external ring was then closed by four double stitches of chromic catgut, passed I was extremely careful in defrom side to side nuding the inner surface of the abdominal wall to get a large raw surface at the internal ring, so as to gain firm union at that point, and the patient was kept on his back for four weeks, yet it gave way a few days after letting him up I shall repeat the operation if he is willing

DR H R WHARTON I have no personal experence with Macewen's operation for the radical cure of hernia, but I have seen two cases in which Agnew's operation was employed, and three or four in which McDowell's method was resorted to, these are subcutaneous operations, and do not compare with this open operation in thoroughness The immediate results seemed good in the cases referred to, but in a short time the hernias were down again Recent reports from England, though still too recent to The allow us to estimate the permancy of the cure, are very encouraging As to Macewen's operation, I removed five of the nine external stitches, and on think it one of the best that has been proposed, and the twelfth day the remaining four There was no if any radical procedure is to be undertaken it The highest temperature was seems to promise the best results Of course, any He had then two chills, the first on the operation is more apt to be successful in children than in adults

Dr C Dulles I would like to ask Dr Keen if any appliance other than the bandage was used after the patient began to go about The hernia looks as if it had been down some time, and not as if it had descended recently I think it would be At this time I examined him, and found the best not to trust solely to the strength of the tissues herma perfectly cured He was then allowed to get for a little while after the operations There is a up, a spica and compress being applied Examining | point in the mechanics of hernia that I have noticed, and which I have not seen described by others, and that is, that a patient with an inguinal hernia usually has a pendulous abdomen I was curious to see if quiring four double sutures Now it will only admit this spare patient of Dr Keen's would follow the rule, and I saw that he did I may lay too much stress upon the matter, but I believe that the best appliance is not one that makes pressure over the ring alone, but one that corrects this abdominal outline, and changes the direction of the thrust of the intestines from one at right angles to the plane of the hernial opening to one parallel to its plane Such an abdominal supporter as women wear would answer the purpose, and I believe it would add to mal wall, and the pertoneum was disected for half an the chances of permanent success after operations for the radical cure of herma.

Of the cause of failure, I can only Dr Keen was tied to the lower part of the sac, and a series of say that apparently the reparative power did not stitches taken from the lower portion of the sac to suffice to obtain adhesion of the sac to the abdom its mouth This stitch, by means of Dr Ellwood inal wall. Why, unless the two chills referred to

had some influence, I do not know practice of those who have had a large experience the antiphlogistics, with aconite, veratrum, large with these operations has been not to use any truss I cannot agree with Dr Dulles He is right as to the shape of the abdomen, and in correcting it to a more oblique outline, but the pressure will always be at right angles to the abdominal walls anteriorly, and not down into the pelvis That would, however, correctly express the direction of the rebound to the exact time when the hernia reappeared I can-When I examined him, February 15, four days after letting him up, it was not there I did not see him again until February 21, when I found it had reappeared I shall not wait long before re-He wants to be earning peating the operation wages, and I do not want to burden the hospital with any patient longer than necessary Any danger will have passed over in a week or two, and I will then operate if he consents

DR Dúlles When we bear in mind the comparatively mobile state of the contents of the abdomen, we must see, of course, that the intra-abdominal pressure is exerted in all directions, and we might draw any number of arrows to indicate it, but there is only one direction of "thrust," which is the resultant of all the lines of pressure, and by supporting the abdomen, as I suggest, by a firm and comparatively unyielding support, we turn the direction of that thrust into a line following the axis of the pelvis, and

take it off the ring

CLINICAL SOCIETY OF MARYLAND Stated Meeting, February 3, 1888

PRESIDENT, N G KEIRLY, MD, IN THE CHAIR b lı١ RAM Woods reported W(ASES OF HALLUCINATIONS DUE TO THE be STRATION OF SODIUM SALICYLATE of sodium salicylate to relieve the pain duration of some of the intra-ocular Iı now, I think, generally recognized I wr tis are the inflammations specially tomy Nor is its good action eatment last y supposed, to these cases having Th⊦∖ Intis, clearly due to syphilis, for ve!' yon of rheumatism, I have severai the wet somuch heved by the salicylates the san'e best course, but the salicycontain wer the of aborting the attack weak soliter of the of epithelial w weak solid par pare of epithelials its raid add one developed area of perations in consulta not operation of the its raid add on the pyonephrosi tion of the its raid of the peration of the p he system must be ence of the drug, s fact gives us a doses of the tion of the let to and dorn, December 25, we were the addorn fully and skilful ac the addorn Death occurred with the action of the course of t ang the heart's These reepression cle, and es not

The usual sodium salicylate—if given in large doses—among doses of quinine, etc Still, I can hardly believe that all the antiphlogistic effects of the salicylates are due to their depressant action on the circulation Other drugs which lower the blood pressure—for instance, the bromides and those already mentioneddo not sensibly relieve the pain nor affect the course There seems to be a selective action which of iritis we little understand The large doses required often produce effects which are not only disagreeable, but may, in exceptional cases, become dangerous Nausea, tinnitus aurium, deafness, fulness in the frontal region of the head, wakefulness are the symptoms The amount which will pro commonly met with duce these physiological effects usually stops the in flammation, or by its failure, induces us to use other More rarely, violent purging, involuntary means evacuations, great dyspnæa and collapse are ob-Professor Chisolm, of this city, served (Bartholow) reported two or three years ago a case of purging and involuntary evacuations occurring in a patient, who took, through a mistake of the druggist, 192 There were, in addition, grains instead of 24 marked depression and weakness, but the patient The force of the drug fully recovered in two days is sometimes expended wholly upon the nervous Such extreme effects as complete deafness, ptosis, strabismus are mentioned in our text-books as having been occasionally observed mentions a case of amaurosis due to the administra-There was no retinal lesion tion of 125 grains Delirium and visual hallucinations are nervous phenomena more commonly observed than those just mentioned Brinton says "Salicylate of sodium in some persons tends to cause most disagreeable visions, whenever the eyes are shut, and I have seen it have this effect even in such a small dose as 5 grains" (Materia Medica) According to Bartholow, it is specially apt to produce delirium in drunkards In the British Medical Journal of January 29, 1881, Dr Bastian presents a series of five cases of delinium and visual hallucinations following the use of sodium salicylate in acute rheumatism One case was that of an old toper, and the character of the delinum was similar to that of delerium tremens the rheumatic poison seemed to be specially virulent, and the delirium was more like that sometimes ob served in acute rheumatic fever, and due only to the rheumatic influence Dr Bastian concludes that if the patient's condition is such as to predispose to delirium, the salicylate will probably precipitate the attack, which, in its characteristics will resemble the delirium occurring in the predisposing disease Cases, however, are here and there recorded in which, like those immediately to follow, there was no pyrexia to produce the trouble, nor any influence which could be held responsible except the salicylate

Case I —Mr J S age 43, occupation journalist, consulted me April, 1886 He had had iritis in the The iris was muddy, the pupil contracted, the periphery of the iris bulged forward, and there was pus in the anterior chamber facts place Pain was intense not only in the eye, but in the

temple There was no syphilis, but an attack of office, seemed to offer an explanation for his iritis heart trouble He gave a distinct history of phthisis in the family, and while I could not find a cavity in either lung when I examined him, there was dulness over the apices of both lungs, there was considsometimes very troublesome I have not seen him Undoubtedly he has fallen a victim | fects growing weaker His habits were temperate He said to phthisis sometimes, a little whisky at bed time him 20 grains salicylate sodium every four hours greatly improved, he asked colored women with a child on her lap sitting on the they introduced themselves On learning this, he said one there make me sure" On questioning him, I found he chamber and found his hand came down upon the sofa between 10 AM, and 10 PM, the day before, mak- his body-servant was in the contiguous room in bed a little while he noticed his ears buzzing could not sleep, and soon thought he was having a of the previous night, he said his mind that it was all imagination, laid down again, and talked away at his son as much as ever, so much so that his wife asked him to stop talking After awhile the delirium changed and he thought he was at the telephone in his office, and couldn't speak above a whisper He got out of bed two or three times during the night to answer a supposed telephone call In the morning, while coming to town in the cars, he was troubled by seeing a black cat on his knee he do this than they would all come trooping back as real as ever His pulse was about 80, temperafrom giddiness ture normal and found it free from albumen

out for me the following notes

Case 2 — L G, aged 50, of temperate habits, has rheumatism three months previous to his visit to my been for ten years troubled with repeated attacks of Each attack runs its tedious course specific iritis There was, so far as I could make out, no organic of six weeks or two months under the orthodox treatment of 10d pot and mercury with the local use of atropia and an occasional application of leeches Four years since the treatment was to the temples changed to the salicylate of sodium in 25 gr doses erable emaciation, and he had a cough which was given four times a day The drug alleviates very promptly the inflammatory attacks and enables him since I discharged him in the spring of 1886, after often to get out in a fortnight-a marked shortening his iritis had gotten well, but he wrote me, from his of the paroxysm. In his case the remedy is not home in Baltimore County, during the past winter without its detractions. It does not disturb very that he had been obliged to give up nearly all his materially his digestion, but when continued for work, that his cough was incessant, and he was some days produces very curious psychological ef-By the fourth day of taking, particles of dust become conspicuous against white surfaces and polhe usually took a glass of sherry with his dinner, and lute the water which he drinks The particles cov-I applied ering his white bed-spread grow in size into green a compress bandage to his eye, ordered the instilla-|flies, and some of these develop into green frogs, tion of a 4 grain atropia solution, and prescribed for with a few green snakes They are not stationary but are in constant motion He knows them to be When he called at my office the next day, I was en- an illusion, but they look very real notwithstanding gaged, and he sat in the waiting-room about half an If the medicine is stopped at this stage of the men-After I had examined his eye, finding it tal disturbance in twenty four hours they are all re-"Doctor, is there a big moved, disappearing in the transition forms in which Should it be needful sofa in the other room?" I told him I didn't think to continue the large doses of the salicylate, figures there was, but to satisfy him, I looked and found no of men, not always with the most pleasant counte-"I wasn't sure nances, appear on the scene At one of my morn-I didn't see her until I had been in the room | ing visits my patient reported his night's sleep much a little while, and then she wasn't clear enough to disturbed by the intrusion of three men into his In waking, by the dim light of the turned had, to settle the question in his own mind, gone up down gas, he saw three men inspecting his box of to the sofa, and tried to touch the supposed woman, valuable papers, which they for convenience had He transferred to a side table He reasoned with himthen told me that he had taken four of the powders self that no one could get into his house, and that ing 80 grains in all He retired about 10 o'clock, could shut out the vision by closing his eyes. At my and did not take a stimulant that night After being visit he was sitting facing an open door leading He into the next chamber After describing his visions "Now I know perdispute with his son He sat up in bed, made up fectly well that there is no one in that room, pointing to the door, and yet there stands in a threatening attitude a big man with an ugly club I can shut him out by shutting my eyes, but there he is all the same"

On another occasion, after using the salicylate for some days, with the recurrence of motes, then flies. frogs and snakes, always green ones, I found him at midday sitting in the dining-room As soon as I had examined his eyes and found that the injection had He could convince himself that these nearly disappeared he said that he was very glad of things were all hallucinations, but no sooner would it, and could now stop the sodium because the hallucinations were becoming annoying Just before I When standing alone he suffered had arrived, a mouse had come out from under the After playing about on the rug it commenced I had him pass his urine in my office, to puff up and became a cat The inflation continued, The salicylate was the animal becoming larger, until it assumed the ap-He slept very little that night, but the pearance of a tiger, upon mischief bent When the next day seemed completely himself The iritis was animal crouched with the intent of springing toward afterwards treated with kal iodid and the alkalies him he asked his mother, who was reading the morn-The other two cases occurred in the private pracing paper at the window, to come toward the fireplace tice of Professor Chisolm, who has kindly written In doing so she got in between himself and the threatening animal, and the illusion vanished During these to take care of it conditions of mental excitement the reasoning powers lirium takes the form of mania, and the patient is were never disturbed, nor did the conversation at violent any time indicate otherwise than a clear head this case the physiological influences seemed always cause delirium, the question of diagnosis becomes to run in the same channel occurred to him on several occasions at many months salicylic delirium is to be distinguished from that due of interval, and always in a regular order. After the rheumatic influence by the absence of fever and three or four days taking large doses of the salicylate lessening of the joint pains at the time the delinum he would mention to me "Doctor, I saw the little occurs" This was so with his cases, and with those pieces of stick in my basin this morning, the flies reported by Dr Bastian will come before the day is out "

Case 3—Miss S, aged 50, had been operated upon for double acute glaucoma Vision had been reduced to light perception before operation, and was so perfectly restored that she could use her eyes for hours daily in confined literary pursuits Four years all after the iridectomy, her left eye was attacked with mens), it is to be diagnosticated by "the absence of a sharp inflammatory attack, which she conceived to be a return of her glaucomatous trouble I saw her after three days of suffering, and found an acute attack of iritis, with some pus in the anterior chamber, a heavy rim of injection around the cornea, a very painful eye with very dull vision sodium was given in 25 gr doses, four times a day By the second morning all congestion had disap-The media had cleared up in a wonderful manner, and vision had returned She stated that she had had a most horrible night of hallucinations of most disagreeable forms. She was very glad to know and feel that the eye was so very much better She had made up her mind, from the horrors of the preceding night, that she could not take another dose of the medicine, even if the safety of her eye depended upon it

In my own case, and the last of Prof Chisolm's, the delirium came on during the first ten hours of the administration of the drug In the Practitioner, for May, 1882, Dr C S Coulston publishes an interesting and exhaustive thesis on "The Use of the Salicylates in Rheumatism " Speaking of this delirium, he says that it usually comes on within the first eight hours, and is due to overwhelming the nervous system with large doses before tolerance is established, which can be readily done aurium appears, the salicylate, Dr Coulston thinks, should be discontinued until the tinnitus has gone Then the salicylate can be given with freedom Each of the five cases reported in the British Medical Journal by Dr Bastian afterwards took the med-In the extremely interesting icine without trouble case (the first narrated by Prof Chisolm), the medicine seems to be well borne for three days, and then Tolerance is not established the delirium comes This case also opposes the remark of Brinton's that the hallucinations only appear when the eyes are edge that the objects seen were hallucinations, but spoken of, in therapeutical value, of the preparations they could not be permanently driven away patients were, on this account, not greatly terrified Dr Coulston states that the hallucinations are usually of a harmless, non-terrifying character ner was the baby of an intimate friend, and he had been received with such favor is that known as liquot his patients insisted that a bundle of rags in the cor- country also

The Albuminates in Medicine-A Large Lee Re fused—Diagnosis and Treatment of Ruptured Intes tine without External Wound-Sanitary Registration of Buildings-Increase of Population of England and Wales—Cremation in England

The albuminates are a class of medicine which is coming into extended use, and one of the most highly of iron, is that which falls into this category In Germany albuminate of iron has already been suc cessfully introduced into medical practice and will One of doubtless sooner or later be put upon its trial in this The particular preparation which has

ferri albuminatic "Drees," which besides the advanwith which it is absorbed from the circulatory fluids Of dried egg albumen 2 5 parts are most suitable dissolved in 30 parts, (all, including the following, by weight) of cinnamon water, forming solution No 1 Then 12 parts of liquor ferri perchloride are diluted soda immediately added The whole is thoroughly The product is a agitated until completely mixed reddish brown, somewhat oleaginous looking liquid with a sweet taste and a slight alkaline reaction is miscible with all proportions of water, and with milk, or other albumen rich fluids, without precipita-The former liquid forms a suitable vehicle for its administration, and the dose is from one to four teaspoonfuls several times a day Prolonged boiling will not separate the albumen of the preparation

Mackenzie has been offered to go to America to see a patient, is probably the biggest thing in the way of a single fee that has been heard of in these days Sir Morrell himself got £1000 for going to Cannes to see Mr Stirling Crawford, and Dr Hahn had the same amount for coming from Berlin to Mr Montague Sir Henry Thompson received £2000 (of which he returned half) once, but these are trifles compared with the fee Mackenzie has declined

Speaking at the London Clinical Society upon the diagnosis and treatment of ruptured intestines without external wound, Mr Mayo Robson said that in some cases of ruptured intestine the symptoms were so distinct as to be pathogenic, that other instances of abdominal injury might present most of the signs of ruptured intestine and yet recover, the shock being due to disturbance of the sympathetic nervous system, and the liver dulness diminished by distended intestine, that the usual symptoms might be entirely absent for a time, only becoming evident after some hours, and that a failure in diagnosis might occur from injury to other regions taking the attention from the abdomen With regard to the diagnosis Mr Robson considered the signs and symptoms separately, and then collectively, remarking on the variability of the cause, the difference in the degree of shock, the usually rapid and feeble pulse, the constant presence of vomiting and pain, and later the usual signs of peritonitis, but especially dwelling on the importance of altered liver dulness, which when normal was almost proof of absence of perforating wound of alimentary canal, when diminished was suspicious of perforation, but when absent was almost pathogenic of rupture He considered the symptoms most to be relied on were shock, more or less severe, following immediately on an accident, pain in the abdomen, moderately quick and flabby pulse, vomiting of contents of stomach, followed by bilious vomit, could be placed upon the expectant treatment, and torum

that the only hope of success lay in early operation tage of being less unpleasant to take than any other For his own guidance he had adopted the following iron compound is also preeminent in the readiness rule. In cases where there was a reasonable belief that the intestine was wounded, as evidenced by the The following formula at present is found to be the history, symptoms and signs, exploration by a small median incision must be made, when if there were any rupture of the bowel, flatus or serum, tinged with blood or purulent material, would escape through the small peritoneal opening which could then be enwith 40 of water and 12 of spirit, forming solution larged and necessary treatment adopted, but should No 2 These two are then mixed together, shaken, no flatus or fluid appear and the peritoneum prove and 1/2 a part each of liquor ammonia and liquor to be healthy, the small wound could be closed and no harm would have been done

A Conference has been held at the Society of Arts, under the Presidency of Sir Joseph Fayrer, to consider the sanitary registration of buildings, with special reference to the bill which is to be promoted in Parliament during the coming session In the course of a paper the objects of the bill were defined as (1) to seek to protect the community against the unsanitary conditions in public and semi-public buildings, and (2) to encourage attention to the sanitary state of The fee of £6000, which it is stated Sir Morrell private dwellings Dr Brudenell Carter moved a resolution declaring the expediency of a compulsory inspection of all public and semi-public buildings with a view to their being properly certified by a competent authority as fulfilling the requisite sanitary condition, and also advocating the establishment of a public sanitary registration office The resolution was unanimously carried

The Registrar-General's returns for 1887 show that the increase of population of England and Wales during the year, as estimated by the excess of births over This is 11,000 less than the deaths, was 355,440 increase of the previous year, showing that the falling off in the rate of increase is not only maintained but has even been accelerated According to the rate of increase from 1871 to 1881, it should have been 23,669 more for 1887 than it actually has been According to the Board of Trade returns, the emigrants from the same portion of the United Kingdom numbered 172,324, thus leaving a net increase in our poplation of 183,106, without allowing anything for immigra-The death-rate last year was 188, a figure which is less than it has ever been since the commencement of civil registration in 1837 Indeed so steadily has the death-rate declined during recent years, thanks no doubt to improved sanitation, that it is estimated that England and Wales contained at the end of last year more than 400,000 persons who would have been dead had the death-rate that prevailed from 1871 to 1880 been maintained The total population of the United Kingdom in the middle of 1887 is estimated at 37,091,564, of which 28,247,151 were in England and Wales, 3,991,499 in Scotland, and 4,852,914 in Ireland

Cremation in England, according to the returns of the Cremation Society, appears to be gaining in favor, as during the present year they have cremated five bodies at their working crematorium. In the case of a child eight months old, the ashes weighed only anxious countenance and diminished or absent liver eight ounces. Up to the present time thirty-one Mr Robson remarked that no rehance cremations have occurred at the Society's crema-

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Relations of Summer Diairhaa and Cholera Infantum to the Weather-Hospital Saturday and Sunday Fund

At the last meeting of the Academy of Medicine in February Dr A Seibert read a paper on the relations of cholera infantum and summer diarrhoea to the weather, which showed a most commendable degree of industry in its preparation These statistics bring to light a number of interesting points, some of which are in opposition to the views generally held by the profession and the laity, but it is to be noted that exception was taken to some of his conclusions by the speakers who took part in the discussion on this occasion

The paper was based upon observations made during a period of ten years, extending from January, 1878, to January, 1888, in the children's department of the German Dispensary of this city, and was illustrated by a large number of charts The cases studied included, he said, all those of acute gastrointestinal catarrh, occurring in children under the age of 5 years, which were treated at the Dispensary during this time As was naturally to be expected, the largest proportion of cases occurred during the summer months and the smallest number in the winter months His statistics, as well as those of the Board of Health, however, he claimed, showed that the disease existed all the year round (even in the coldest weather), and that the proportionate mortality was just the same in cold as in hot weatherabout one case in every four proving fatal

It was a somewhat remarkable fact, he went on to say, that the number of cases and deaths was always much greater in the month of July than in August Thus in the ten Julys there were 2,443 cases at the Dispensary, and in the ten Augusts only 1,524, while summer month, and of every day of each month, the number of deaths reported in the city of New during the last ten years, had led him to the follow York during the ten Julys was 12,428, and during the ing conclusions ten Augusts only 6,205 The reason for this difference, he thought, might perhaps be explained by the fact that it took a few months, after the warm weather had set in, to fully arouse the tenement-house population to the danger to which their children were exposed from this disease, and to the necessity of taking suitable precautions as regards diet, fresh air, sanitary conditions, etc., for its prevention

During the summer months Dr Seibert said that it was found that the number of cases and of deaths bore no relation whatever to the rise and fall of temperature, and the same was true as regards the range of humidity, so that warm moist weather did not predispose more to the disease than warm dry weather He stated that he had also made a very thorough in- furnishes the principal food of so many young chil vestigation of the effect of light and heavy rain-fall, but totally without result been a favorite idea with him that want of water on from the time it left the cow the upper floors of tenement-houses constituted a a question of how far the decomposition of the milk somewhat important factor in the causation of sum- had advanced by the time it was consumed by the

mer complaint in the city Local rain-falls also had no effect, and the same was true in regard to the velocity of the air-current

He believed it to be still a disputed point whether direct heat is capable of causing the disease in question, and he had accordingly made a special study of all the hot days in the ten summers—when the thermometer rose to 85° or higher According to prevalent opinion, the months containing the greatest number of hot days ought to have had the greatest number of cases and of deaths, but he had found no evidence supporting this view Thus, in the last two weeks of June, 1880, there was a large proportion of these hot days, and in the same period of 1887 there were but few of them, yet the number of cases was just about the same in both of the fortnights mentioned Again, in July, 1881, when there were but few hot days, there were 290 cases, while in July, 1887, which was considerably hotter, there were only 196, a ratio

How, then, were we to account for the fact that in the warm months there are always such a large num ber of cases? It was evident, he said, from the facts just pointed out, that hot weather was not necessary for the production of the disease In regard to warm weather, however, the case was different, and the statistics collected showed that in the early part of the summer season, as soon as the minimum daily temperature reached 60°, and this continued for a few days, an increase in the number of cases of acute Furthermore, gastro-intestinal catarrh was noticed if the minimum daily temperature remained above 60° for a number of days (say for a week or more), it was noticed that the disease became epidemic The reverse of this was noticed at the close of the warm season in October, the month of departure During the first half of the month the minimum daily temperature usually reached 60°, but in the latter half, when the colder weather set in, the end of the epidemic occurred

To sum up, an examination of the records of every

1 Hot weather, either dry or moist, is not neces sary for the epidemic appearance of acute gastrointestinal catarrh

2 Warm weather, either dry or moist, showing a minimum daily temperature of not less than 60° brings on the epidemic every year, irrespective of the maximum daily temperature

3 The disease loses its epidemic character as soon as the minimum daily temperature falls below 60°, as in October

4 Therefore, this disease cannot be brought about by the direct effect of high temperature upon the child's body

Dr Seibert then went on to speak of the milk that It was often carried long distances, he said, Previous to this it had being much jolted about, and absorbing impurities It was, therefore, only

retarded decomposition, and Dr Cyrus Edson, of the New York Health Department, had informed him that in his experience he had found that milk usually began to turn whenever its temperature reached 60° or higher Chief Engineer Birdsall, of the Department of Public Works, had also informed him that milk was the chief exciting cause of the trouble He whenever the temperature of Croton Lake rose to 60° or above, there was a peculiar taste to that water which he attributed to the decomposition of certain matters contained within it

In the discussion that followed the reading of the paper Dr L Emmett Holt said that in summer there were different forms of diarrhoad disease in young children, and that he thought it advisable that some distinction should be made between them In the production of what is ordinarily known as summer complaint he believed that there were four principal stances in cold weather factors concerned, viz 1, heat, 2, feeding, 3, sanimost important of these factors was heat

Dr Holt as to the importance of distinguishing between the different forms of disease met with had seen cases in the warmest weather in which an aggravation of the symptoms resulted from reduction of temperature The child took cold, and the disease was then apt to assume a dysenteric tendency weather, as he believed the latter to be an entirely to give rise to diarrhoea different affection from the former In the cooler ferent that it was unjust to classify the two diseases together, although the lesions might be the same The difference between the two was as great as that between the bronchitis incident to pertussis or measles and idiopathic bronchitis

It seemed to him, also, that one might be misled by the number of deaths reported Thus, many of the deaths occurring in August or September might be children who had contracted the disease in the earlier part of the summer The mortality, as a rule, was somewhat greater in September than in May, although the temperature was usually higher in the latter month than in the former, and the reason was because many of those dying in September had been taken ill in one of the previous months

It could be stated in a general way, he thought, that the disease known as summer complaint was caused by heat, but in what way the heat operated to produce it was not as yet clearly ascertained was evident that heat alone was not sufficient for its production, or else the disease would be found prevalent in the country as well as in the city It must be a fact, therefore, that there were certain causes which were brought into operation by the unsanitary conditions met with in the city in hot weather, and the opinion was gaining ground among the best ob servers that summer diarrhoea is a microbic disease In Asiatic cholera, the causative agency of Koch's braillus had been pretty generally accepted, and it

It was well known that a low temperature to the intestines by its actual presence, and not by causing decomposition of food In like manner, it did not seem unreasonable to suppose that microbes might act in the same way in some cases of summer diarrhœa

Dr Caillé said that, in his opinion, decomposing believed, also, that high temperature sometimes does have a pernicious effect upon the human body, and thus serves to pave the way for some agency which will give rise to the diarrhœal trouble It was a fact that children nursed at the breast, or brought up on some of the numerous infants' foods in the market, who never get cow's milk, will sometimes be attacked with serious gastro intestinal disease if allowed to overload their stomachs in hot weather, while they will suffer but little, if at all, under the same circum-

He then quoted some experiments made by two tary conditions, and 4, constitution, and that the French physiologists on animals exposed to a continued temperature of 104°, in which the phenomena Dr J Lewis Smith said that he quite agreed with observed to result from this exposure were 1, increase of nervous excitability, 2, nervous depression, He and 3, convulsions, coma and death The same results, he said, had been noticed to be produced in children when the weather was very hot It was his opinion, therefore, that while high temperature did not directly produce diarrhoa, it did have a perni-He thought there was perhaps a fallacy in comparing clous effect upon the system, and under these cirsummer diarrhœa with the diarrhœa met with in cold cumstances any irritating substance would be likely

As regards the smaller number of cases of summer months the causes of the trouble were usually so dif-complaint, as well as of deaths from the disease, in August than in July, he thought that perhaps one reason for this was that a much larger number of children left the city in August than in July, while those which remained had the advantage of the numerous fresh air excursions then provided for the

> The President, Dr A Jacobi, said that there was a great difference in the cases observed The larger number were of a simple catarrhal nature ers, where the discharges were serous in character, there was a tendency to collapse In such cases the lesions found in the intestines after death might be very slight, while several of the organs of the body might be found to be in an advanced stage of granular degeneration He believed that great heat would kill by its direct effect upon the muscular system, including the tissue of the heart itself, the high temperature having the effect of coagulating the myosine of the muscles Intense heat also had a certain influence on the surface of the body, causing an immense dilatation of the blood-vessels cient nutrition, particularly of the brain, would result from this, and thus collapse would be brought about These were the cases of true cholera infantum, which generally terminated fatally, and which were liable to be met with in well-to-do families as well as among the very poor The large majority of the cases met with, however, were of gastro intestinal catarrh

Dr Jacobi said that he had been much interested was believed that this micro organism was received in the fact demonstrated by Dr Seibert's investigathrough the mouth and acted as a source of irritation tions, that 60° was the turning-point for this disease,

and it was especially noteworthy in this connection that Dr Edson had expressed the opinion that milk began to decompose, and Chief Engineer Birdsall the opinion that water began to be affected by decomposition, also at 60° In conclusion he made some remarks in regard to the importance of proper ing the After-treatment of Cataract Cases," by Dr

The annual collection of the Hospital Saturday and Sunday Association amounted this year to the handsome some of \$50,408, which, notwithstanding the withdrawal of the Presbyterian Hospital from the Association, renders it possible to distribute among the hospitals entitled to a share of the undesignated contributions some \$6,500 more than last year

NITRITE OF AMYL IN DYSPNŒA

Dear Sir — The Journal of January 21 contained an editorial comment on the use of "Nitrites in Asthma," as observed by Professor Fraser, of Edinburgh, wherein it was stated that the nitrite of amyl, formerly given by inhalation, produced the same effect with much longer continuation when given by the stomach

At that time I had a patient with Bright's disease, who suffered most agonizing paroxysms of dyspnæa —they were simply terrific, notwithstanding the use of ordinary measures There was no asthma what-On the recurrence of an attack, after reading the editorial, I gave 3 drops of nitrite of amyl in a teaspoonful of brandy without expecting much result, but simply as a deinier ressort The result was simply miraculous! It was almost instantaneous From a sense of impending suffocation the patient began to breathe perfectly freely in less than five This relief lasted for upwards of twelve hours, when the same quantity was repeated on the recurrence of another attack, with the same result, and without increasing the dose The nitrite was given on every recurring attack until the attacks finally disappeared, and for several days the patient The original disease, has had no dyspnœa whatever however, is unaffected by the nitrite

Now, while I am free to admit that one swallow doesn't make a summer, and while I know that this Paul Schillock, to be Asst Surgeon, with the rank of First remedy is not especially recommended for the dyspnœa of Bright's disease, still, I have seen enough of its effects in this case to make me wish that I could tell my experience to the whole profession at once

THE PATHOLOGY OF HAY FEVER

Read in the Section on Psychological Medicine and Nervous Diseases, Ninth International Medical Congress

BY S S BISHOP, M D,

Synonyms Nervous catarrh, nervous coryza, hay asthma, rose cold, June cold, July cold, peach cold, summer catarrh, autumnal catarrh, pollen poisoning Latin equivalents Catarrhus æstivus, coryza vaso-motoria periodica French equivalents Catarrhe d'été, catarrhe de foin German equivalents Fruhsommer-catarrh, Heu-asthma Italian equivalent Asma dei mietitori

Goethe has tersely said "If a man write a book let him set down only what he knows " In medical literature there is much writing of the negative sort But if a man take an inventory of his mental stock he is forced to admit that a large percentage of it The object of philosophy is consists of negations the knowledge of phenomena in all their relations, and it cannot be attained independently of theories and hypotheses Not less indispensable are the same methods of investigation and reasoning, and not less latitude must be enjoyed, in discussing a subject of the peculiar nature of the one which furnishes the title of this paper One must divest the mind of preconceived opinions before it is free to apprehend causes and conditions in their true proportions Much has been written concerning biology, electricity, phrenology, magnetism, yet who has mastered the principle we call life? What Æolus restrains the electric currents of the world? Who measures the molecular activity of the brain when his own thought is evolved-labels this atom, "love," or that, "causality?" Who can define odylic force, and the law of its operation? But, though our path is beset with discouragements, and our work of irvestigation is hemmed in by the natural restrictions of human thought, and the limitations of our knowledge of pathological processes, the laboratory, lens and logic may yet triumph

The name hay fever is a misnomer. It is employed to designate a condition to which numerous other terms have been applied with equal fitness. To the array of names already in use, ill chosen because they are misleading, I have had the temerity to add another. In a published lecture, delivered in

the Chicago Medical College in 1885, I proposed the term nervous catarrh Since then several authors have adopted this expression One writer, however, calls it nervous coryza, but coryza is from the Greek $n \dot{\rho} \nu \xi \alpha$, signifying only a running at the nose, while the word catarrh, from ματαρρέω, admits of a much broader application and, with properly modifying adjectives, may be used to designate affections of various mucous membranes Coryza is a specific term, catarrh is generic, and obviously is the more correct one to characterize a disease which is not confined to the nasal cavities Nervous catarrh is so comprehensive a term, and is so tersely suggestive of the pathology and symptomatology of certain neurotic derangements, as to be susceptible of a much larger usefulness than has been accorded it To illustrate There is a truly nervous intestinal catarrh which attacks and leaves a certain class of individuals of the nervous temperament as suddenly as an attack of hay fever does I have known a musician to suffer from severe attacks of diarrhœa just previous to his appearance before an audience which he was announced to entertain Immediately after his performance all symptoms of intestinal disturbance would vanish, only to return again at his next appearance in public I might cite a case of an orator of the evening who was similarly afflicted The nervousness induced by the contemplation of addressing his audience would so react on the nervous supply of the intestinal tract as to cause sudden and copious diarrhea No sooner would the oration be finished than all unpleasant symptoms ceased We have nervous dyspepsia occasioned by mental A certain combination of objective and subjective causes operating on one individual produces morbid phenomena referable to the mucous membrane of the turbinated bodies, resulting in an attack of hay fever-nasal nervous catarrh In another, the seat of the resulting manifestations will be in the bronchial mucous membrane, eventuating in an attack of asthma --- bronchial nervous In yet another, the intestinal mucous coats catarrh are the scene of this breaking of a nerve storm, resulting in copious watery discharges-intestinal nervous catarrh All these are undoubtedly coordinate morbid conditions of the nervous system, finding expression in exaggerated and perverted functional activity

cause they are misleading, I have had the temerity to add another In a published lecture, delivered in time of its first description by Dr Bostock, of Lon-

don, in 1819, until the last decade ing upon hay fever as a simple congestion or inflam- reasoning, for it argues the reflex neurotic character mation of the Schneiderian membrane, as eminent English authorities have in the past, and yet do, fever not only in its etiology, symptomatology and prominent American authors favor the neurotic the- therapeutics, but in the morphology of its secretions ory In this connection it is interesting to note that The manner in which exciting causes bring about ata recent writer for the Lancet treats of common nasal catarrh as a reflex neurosis and, in support of his position, adduces numerous instances in which purely nerve-remedies succeeded in arresting attacks of acute coryza

Although I maintain that this malady is essentially due to an abnormal susceptibility of nervous tissue, I do not claim that there exists any organic lesion of stantly thrown into a state of intense excitation, or the nervous centres, to which the disease is attribu- irritation destroys life, and no opportunity is afforded the neuropathologist to make post-mortem observations But if the affection be a reflex neurosis, can we hope for microscopy to determine with precision the condition of nervous structure which primarily constitutes the disease?

If we examine the arrangement of the nervous supply of the respiratory passages we find that it is favorable to the existence of reflex nervous phenom-One sympathetic nervous centre, the sphedopalatine ganglion, supplies branches to the lining membrane of the nose, pharynx and Eustachian It has a motor, a sensory, and a sympathetic It communicates with the facial and pneumogastric nerves, thus uniting in the closest sympathetic connection the nose, pharyny, middle ear, laryny and Furthermore, the Schneiderian membrane is continuous with the lining membrane of the nasal duct and eyelids, the pharynx, Eustachian tubes and tympana, the larynx, trachea and bronchial tubes Ablation of the spheno-palatine ganglion sets up a severe catarrhal state of the Schneiderian membrane A congestion once started in this structure may extend with unobstructed facility to the contiguous membranes, very like the spreading of an erysipelatous inflammation from one area of the skin to an-But the continuousness of the membranes as any mortal throughout these various organs does not satisfactorily account for all the symptoms produced in one functional disease of the nervous system is its heredi part by impressions upon another Certainly an inflammation in the throat may extend along the Eustachian tube to the tympanum, but there is no such reason to account for the sudden transitory tinnitus aurium which occurs in some persons immediately upon the ingestion of a draught of cold water or the inhalation of tobacco smoke, or for the cough which is occasioned by the contact of instruments with the external auditory meatus or with the inferior turbinated body or the septum nasi, or for the paroxysm of sneezing produced by irritating the scalp All these symptoms are examples of reflex nervous impulses, and these intimate sympathetic relations between various portions of the animal economy exhibit nating one in this class of patients—an arguthemselves with exceptional force in patients of nervous temperament

ties may be responsible for the existence of common strengthen my position in this discussion asthma, has lately acquired a considerable following periodicity of the disease points to nothing if not to

Instead of look- in America But this is directly in the line of our of a disease which possesses close kinship to hay tacks in hay fever is much the same as in the case of asthma In a hay fever subject let brilliant rays of light fall upon the retina, or dust impinge upon a sensitive area of mucous membrane, and what oc curs? The end organs of the sensory nerves supplying the part affected, being over-sensitive to the presence of that particular kind of stimulus, are in Immediately the impression is flashed Being a functional disturbance, it never along the sensory nerves to a nervous centre-brain or ganglion, thence, changed to motor impulse, it is switched back, on the one hand, along the vaso motor nerves to the blood-vessels of the seat of irritation, causing dilatation, engorgement, swelling and flux, and on the other hand, along the pneumogastric and sympathetic nerves to the muscles concerned in the act of sneezing, and, through extensive sympathetic nervous relations, all the respiratory tract and its connections may participate in the disturbance and become involved in a fully developed attack of hay asthma—sneezing, coughing, wheezing, nasal flux, expectoration and lachrymation

> Thus it appears, from the manner in which parou ysms of hay fever are started and developed, that there are three conditions upon which the existence First, abnormally suscep of the disease depends tible nerve centres, secondly, hyperæsthesia of the peripheral termini of the sensory nerves, and thirdly, the presence of one of a large variety of untating Exclude one of these conditions and the Allay the susceptibility paroxysms are prevented of the nervous centres by certain cerebral sedatives and an attack is averted or arrested the nervous supply of the over-sensitive areas and the result is the same Remove the patient beyond the reach of exciting causes and he is as comfortable

Another fact in support of the theory that this is a tary character I might quote many illustrative cases were there time, but three representative ones will In Dr Morrill Wyman's family there were suffice six sufferers from hay fever besides himself In the family of the Rev Henry Ward Beecher there were two besides himself, and in the family of Chief Justice Shaw there were six members who had different forms of this distressing malady To be sure, heredity alone does not establish a neurotic character, but, taken in connection with all the other facts in the case, it 15 2 weighty argument in support of the assertion that this is a constitutional disorder of a neurotic type

Again, the nervous temperament is the predomi The same may ment which needs no elucidation be remarked concerning asthmatic sufferers, and the The theory that lesions situated in the nasal cavi- admitted kinship of the two diseases only serves to

its nervous nature, for one cannot conceive how the claimed to be cured pollen theorists, from their point of view, can recon- is not a simple local inflammatory disease they will reach the nostrils of sufferers in their vary- well as of the perceptive nerve centres forms of the malady strengthens the nerve theory, while it weakens the pollen argument, for it shows that the disease exists under conditions which are the least favorable to the operation of pollen, in fact, where the pollen theory is inadmissible-in the winter and spring I do not wish to convey the impression that I undervalue the importance of pollen as an exciting cause, but I do wish to be understood as maintaining that it constitutes but one of three factors which render the existence of the disease possible

Other arguments that may be briefly mentioned are the suddenness of the onset and disappearance of attacks, the fact that the most potent palliatives are nerve sedatives, tonics and stimulants, and that fruit, etc

or arrest paroxysms

The chief argument urged against the nerve theory hypertrophies, etc., concurrent with hay fever, is not for the time surprising in this catarrh-producing climate Indeed, the diseased turbinated tissue may be a coincidence or sequence, rather than the cause, for it is natural to suppose that years of constantly recurring attacks of even a functional disturbance of the vaso motor supply of these parts would result in a passive hyperæmia which would eventuate in proliferation of cells in the mucous and submucous tissues, and the growth reception and retention of irritating agents argument that this condition is responsible for hay Association fever in infants, youths, and even in adults in whom there is no evidence of inflammatory changes before the expression may be permitted hay fever, and many cases have been so treated by American physicians during the last three years However, the most sanguine practitioners of this Cases that were supposed to have been phasize the truth in the nerve theory the results cured still suffer

This points to the fact that it cile this feature of the complaint with their own doc- were the treatment should be attended with success Is it reasonable to assume that the pollen of For reasons which I have set forth one cannot expect various plants which give rise to attacks in different this method to cure all, but, granting that it may cure individuals will be set free to float away on their fruc- many, the nerve theory would not suffer in the least tifying pilgrimages on exactly the same day, and at by the admission, for it assumes a pathological connearly the same hour, each recurring year, and that dition of the receptive end organs of the nerves as ing localities and situations and vocations simultane- the susceptibility of either the central or peripheral ously year after year? The variations that occur in nervous system, and you remove an essential element the yearly advance of the seasons preclude this hy- in the disease-destroy its entity. But what shall we And again, the identity of the different say of that other large proportion of patients in whom paroxysms are produced by irritation of the retina, the scalp, etc, or by chilling of the skin? Are we to be logical and, reasoning from analogy, must we destroy the sensitive area, the retina, enucleate our patients' eyes, scalp or skin them! Yet, if you follow the reasoning of this school of theorists to its logical conclusion, it will lead you to this reductio ad absurdum

The neurotic theory is supported by the nature of the following causes Electric and gaslight, overexertion, anxiety, indigestion, dampness, chills, camphor, gases, feathers, perfumes, odors from animals, dry, hot and impure air, various kinds of It will be observed that pollen and dust mental emotions and physical exertion may prevent do not necessarily enter into the causative nature of these excitants

This theory receives support also from the fact is that many hay fever patients have diseased nasal of the excessive irritability and nervousness which But we may say the same of that much patients experience just preceding and during atlarger proportion of our population who have no tacks. The coordinate action of muscles is affected, knowledge of hay fever. That we should find nasal and they complain of feeling jerky and ill-tempered

In studying this disease it should not be forgotten that the statements of sufferers relative to the history and phenomena of their maladies should be given greater credence than is usually accorded the assertions of other classes of patients, masmuch as they enjoy the distinction of being superior to the average in intelligence and culture This is far from being an idle assertion, for it voices the experience of the best of hypertrophies which might serve as a midus for the authorities and is borne out by a reference to the list But the of membership of the United States Hay Fever

I cannot consider the treatment of this subject as approaching completeness without referring briefly to or between attacks, is not tenable The paroxysms two other important points Microscopists have been do not so much resemble symptoms of an inflamma- recently examining the nasal and bronchial secretions tion as they do an irregular and explosive discharge from hay fever and asthmatic sufferers, with the result, of a superfluity of nervous force—a nerve storm, if it is claimed, of establishing the kinship of the two It has been diseases by demonstrating the presence in both of claimed that destructive treatment of the sensitive products called gravel It is believed that this soareas in the nasal cavities would permanently cure called gravel accumulates in the secretions of the respiratory passages, and acts as a local irritant, in the same manner that any foreign body would

The force and analogy apparent in the following method have recently confessed disappointment at facts relating to neuroses of the skin serve to em-Others are only slightly benefited, ing over the surface of the whole body may be prowhile a few are worse for the operations So far as I have been able to obtain definite data, they demonstrate that not one-half the number treated are liver, etc Neumann says "There is no doubt that a large proportion of cutaneous diseases depend upon disorders of the vaso-motor nerves which cause certain derangements of circulation in the arteries, veins and cutaneous glands Anæmia and hyperæmia of the skin happen from vaso-motor irregularities, some from the brain, some from the spinal cord, or from the action of cold, or the electric current, etc." Now, since it is admitted that there are both immediate and reflex functional nervous disorders of the recorded facts skin, with what show of reason can it be denied that there are similar neurotic disturbances of that other reasonable evidence that the products of, or emana skin which covers the interior surfaces of the body? The latter membrane is more vascular, more delicate, more sensitive, more highly organized than the skin It possesses susceptibility to all agents which affect the skin, and to many others besides For example, notious gases, to which the skin is insensible, will irritate the mucous lining of the respiratory organs The same laws that govern the action of the vasomotor nerves of the skin also regulate the vaso-motor If itching and supply of the mucous membranes burning of the skin are produced by morbid alterations in the ovaries, so is pruritus urethræ produced by disease of the bladder, pruritus nasi is generally accepted as a sign of worms in children, urticaria Koch's work, found in the second volume of the Im results from irritation of the gastric or intestinal mucous membrane, so may asthma arise in the same manner or from an irritant applied to the post-nasal mucous surface, ear-cough is occasioned by contact of instruments with the skin of the external auditory canal, and hay fever paroxysms result from irritation of the retina, the upper hp or the scalp, or from chilling the skin

Finally, all the facts in our possession force us to the conclusion that the weight of testimony is in favor of the doctrine that hay fever is a reflex functional

nervous disease 719 W Adams St

THE PORTAGIOUSNESS OF PHTHISIS

Read before the Medical Press Association, of St Louis, January 30, 1888

BY WILLIAM PORTER, MD,

PHYSICIAN TO ST LUKES AND TO THE PROTESTANT HOSPITAL CON SULTING PHYSICIAN TO THE ST LOUIS CITY HOSPITAL, ETC

Before entering upon the discussion of the subject proposed, permit me brief reference to the terms I have chosen the word portagious because it conveys a more exact idea of the manner of transmission of phthisis for reasons hereinafter mentioned, than either contagious or infectious this writing the term phthisis will be used to denote that class of disease to which belongs the large majority of cases of slowly progressive pulmonary inflammations, ie, chronic tubercular phthisis

Pardon me if I decline to enter into a discussion of the relation of the bacillus to phthisis somewhat closely following the investigations of recent years, I cannot conclude whether the bacillus is the cause or product of tuberculosis Cermade, based upon the hypothesis that the microbe is absorption of phthisical matter is a potent cause of a factor of phtasis per se, but rather is our advance phthisis

continually upon the old lines of aiding assimilation, diminishing waste and caring for the hygienic sur roundings So far as our present knowledge ex tends, the bacillus is to phthisis as smoke to fire, it may indicate its existence, but neither incites nor in tensifies the combustion Whatever the develop. ment of theory may do for us in the future, let us this evening limit ourselves to deductions made from

The question I would ask you is Have we tions from a phthisical subject, may be carried to, received by, and cause like disease in one previously free from phthisis?

Believing that the weight of testimony is with the affirmative I will offer the results of

- I Some experiments made as to the transmissi bility of phthisis
 - 2 The practical experience of others, and
 - Personal observations
- I In experiments made by Tappeiner, in 1883, tuberculous sputa being inhaled by eighteen healthy animals, tubercles in both lungs, and pleura were That record of afterwards found in seventeen perial Health Reports, shows that after the inhala tion of material from phthisical cavities, the rabbits and guinea-pigs under observation, had within twenty-eight days, tubercles throughout the lungs of all, and in the liver and spleen of some It is true that many of the masses in Koch's description re semble caseous broncho-pneumonia, but this is also to the point according to the definition of phthisis which we hold

Wargunin, of St Petersburg, in 1884, showed by experimental research in three series of cases, that the nodules of broncho-pneumonia resulted not only from the inhalation of phthisical sputa, but also from other foreign substances

The proposition that tuberculous phthisis is an in fective malady was endorsed twenty years ago by Villemin and Chauveau, who labored to demonstrate that inoculation of tuberculous matter only, would produce tubercle, while Sanderson, Fox and others, claimed the same results from the introduction of other material

Martin, of Paris, within the last few years, how ever, after a number of experiments, which I may not detain you to describe, (Rev de Médicine), seems to have established the following conclusions

(a) Tubercle moculated locally, determines, after incubation, and after a variable time, general tuberculosis, and the virus seems to acquire increased activity by inoculation in series of animals of the same or allied species

(b) But, if we inoculate matter obtained from those tubercles secondary to the injection of non tubercular foreign bodies, it never gives rise to general tuberculosis, and after two, or at most, three terms of the series, it even loses the power of producing a local reflection. ducing a local inflammation

Though we were to admit that Wargunin, Sander son, and Fox have found tubercle to result from in oculation with non-tuberculous material, we would still be justified in maintaining that the inhalation and

The carefully conducted investigations of Cadeac and Mullet recently published, show that while no positive result was obtained from compelling rabbits and guinea-pigs to inspire air exhaled by phthisical carrying particles of sputa, two out of twelve guineapigs acquired tubercle

Permit me to refer to an experiment of my own

Three healthy guinea pigs were selected One was moculated with phthisical sputa, and placed in a small box with one of the The third was confined in a box in an adjoining room They were cared for alike and had similar food In four weeks the first one died, and the examination showed tubercle in the lungs, and a large cheesy gland near the point of inoculation Three weeks after the second animal sickened and was killed I found small granulations scattered through both lungs, at some points aggregated, and in the right lung were two nodules, having a soft cheesy centre

The third guinea pig, examined three months later, had no evidence of tubercle or other disease

The only experiment, so far as I know, upon a human subject was made by Drs Demet, Pararky, and Zallories, of Syra, in Greece, who inoculated, with sputa from a phthisical patient, a man whose history afforded no suspicion of tubercle, and whose lungs were healthy, but who had gangrene due to femoral embolism and who would not permit ampu-In three weeks auscultation revealed evidences of disease at the right apex Thirty-eight days after the moculation, the man died from gangrene, when it was found that the upper right lobe had seventeen small tubercles and two granulations in the apex of the left lung

2 What has been the practical experience of others? One of the most valuable labors of the Collective Investigation Committee in London, is that relating to the transmission of phthisis While the majority of replies to inquiries were unsupported negatives, 261 answers coming from physicians in family prac tice affirmed the proposition that phthisis may be communicated from the sick to the well, and evidence was given in proof of the statement hundred and ninety-two observers recorded cases where both husband and wife became phthisical, in 130 cases there being no phthisis in the family of the one to whom the disease was thought to have been transmitted

Some of these cases were very interesting Dr Spriggs, of Great Bedford, instanced the case of

Miss R, aged 48, a dressmaker, who, hving in rather a lonely cottage at C, Bedfordshire, had three apprentices, young girls from 17 to 19 years of age, not related, from three adjoining villages, who took it in turn to remain in the house and sleep with her, each one week at a time During their apprentice ship, Miss R was taken with phthisis, of which she died In less than two years afterwards, all three apprentices died of phthisis, although in the family history of each, no trace of phthisis existed, and the parents, brothers and sisters of two are alive and well at this time

Another interesting case is related by Mr G F Blake, of Mosely, Birmingham, in which a perfectly healthy child, with a family history free from all trace of tubercle, is reported as becoming infected hemoptysis, after the disease had run a rapid course

The following cases were reported to the Clinical Society of London, by Dr Herman Weber

A young man who had lost his mother, two brothers and a sister, of phthisis, and who himself had twice had hemorrhage from the lungs, had quite recovered, and married at 27, being then perfectly well His first wife was in good health, and came of a healthy family She died of consumption after her patients, yet when air was used collected from near third confinement. The man shortly married again, an "ap the beds of hospital inmates, the air presumably parently healthy woman," and this second wife, after a year of married life, died of "galloping consumption". He again married life, died of "galloping consumption". married a healthy young woman of 25, belonging to an 'ex ceptionably healthy family" During her second pregnancy, she developed symptoms of phthisis, which run a rapid course, and ended fatally in about eight months Undaunted, this man married a fourth wife, a perfectly healthy woman of 23, of healthy antecedents Three months after her first confinement, she began to show symptoms of phthisis, and notwithstanding two sea voyages, died after nine months, with tubercle in liver, spleen, and intestines, as well as in the lungs Though the husband of these four wives, who was a sailor, remained in ap parently good health, physical examination revealed the exist ence of morbid changes about the apex of the left lung

It is possible that the life at sea kept his disease in abeyance,

for when he had to lie by on account of a severe fracture, the disease became active, and he died of consumption within two

A convincing report of a case in which the portagiousness of phthisis is affirmed, served as an introduction to a valuable paper last year by Dr F I Knight, of Boston, and who has not read the evidence offered upon this subject by Webb

I need not further collate records, for you gentlemen, being conversant with medical literature, will grant that new and strong proof of the proposition which we have announced is being constantly given

What have been our own observations?—In more than three hundred cases of phthisis, I have kept a record of the family history, and find that 51 per cent of this number were of families in which some other case had occurred The inquiry extended no farther than to first cousins this would be accepted as evidence in the favor of heredity of phthisis, but I now believe that in many of these cases the disease was acquired by the carrying of the products of disease to a subject whose physical condition favored its reception and development

I recall the case of Mrs L, in whose family was no trace of phthisis Before her marriage, and for several years after, she was the ideal of a healthy Two children were born Her husband, a well-known city official, had phthisis Her attendance upon him was constant, and for some months before his death she and the younger child were with him night and day When called to attend him I found that he had been substituting for the ordinary cuspidore, a newspaper spread upon the floor at his bedside, and this would be loaded with sputa each The case was rapid morning The husband died, and within eighteen months Mrs L and the younger child also died from phthisis, while the elder daughter, who was comparatively little in the sick room, still lives and is well and strong I have the notes of other instances almost as instructive, but this will suffice

From such facts as I have endeavored to give in by a phthisical nurse, and having died with profuse this paper, I believe it is fair to concede the probability of the portagiousness of phthisis

3 How then can the disease be conteyed?-In two ways mainly First, By air carrying particles of disease into the respiratory tract Second, By food from infected sources, through the alimentary tract. The first of these propositions is, I think, proven. Not only are the experiments and records here given, powerful affirmations, but there is in the profession a steadily increasing belief in its truth which would require much more negative testimony than has yet been offered.

I would not be misunderstood I do not think that as yet we can sustain the statement that phthisis is contagious—acquired by mere contact, or infections, if the term be limited to imply a hidden subtile miasm communicating the disease—but I do hold that particles of matter from the site of disease in a phthisical patient may be carried, planted in suitable soil and incite phthisis I cannot think that all are liable to so acquire the disease

I would go further, and say that probably only those may so contract phthisis, who by reason of lowered vitality, through previous sickness or long watching in the sick room, or those who have local congestion or inflammation in the respiratory tract. The fixation of a minute particle of dried sputum from a phthisical cavity, upon a point of irritation in the respiratory tract of a non-phthisical patient, may constitute an effective inoculation. This leads me to express my belief in the possibility of auto-inoculation—in so far as the debris from a tuberculous lung coming in contact with the laryin denuded of epithelium may cause laryingeal tuberculosis

The second proposition that phthisis may be caused by eating the flesh of tuberculous animals, or drinking the milk of tuberculous cows may also be received with the same limitations as the first ie, that there are conditions which favor the development already existing in the individual, and as Mr Law, of Cornell University has well said, this embraces such a large class that the interests involved are almost illimitable

I will not detain you by detailed suggestions as to our duty if the position maintained in this paper be true. There should be frequent change of the atmosphere in the sick room, complete disinfection of all clothing or vessels holding expectorated material, and the close confinement of any relative of, or attendant upon a phthisical patient, should be forbidden

I also believe the day is at hand when the physician will recognize that it is as much his duty to examine the food that his patient eats, or the milk that is ordered for the sick child, as it is his province to see that the drugs he prescribes are pure and well compounded

2830 Locust St

EDUCATION AND REGISTRATION OF PLUMBERS—There is a concerted movement on foot in England and Scotland for the better education and the registration of plumbers. In connection with the national movement large meetings have been held in Edinburgh and Dundee, and representative men have been appointed to form local councils. In Edinburgh Sir Douglas Maclogan is identified with the movement.

MONOCULAR DIPLOPIA WITHOUT MANIFEST LESIONS OF THE AFFECTED EYE

Read before the Chicago Medical Society, February 6, 1888

BY ROBERT TILLEY, M D,

OF CHICAGO, ILL.

In October, 1881, Mr James E Adams, of Lon don, England, brought before the Ophthalmological Society of Great Britain and Ireland the subject of uniocular diplopia. The question was confined to the existence of the phenomenon in the absence of any abnormal condition of the iris, lens, vitreous, fundus or any marked error of refraction of the affected eye, the question resolving itself into this, is it possible for an eye, not the subject of any manifest deformity to project two images of one object? or are two mental conceptions possible from one impression on the retina?

Mr Adam's attention was directed to the subject in connection with a suit for damages against a railroad company by a "hysterical woman" This occurred in the spring of the same year, 1881 The symptoms said to have existed in the case were, insensibility, coming on half an hour after an alleged railroad injury, lasting for three or four days, followed by vomiting, then convulsions, then convergent strabismus lasting for some weeks At the time of the examination by Mr Adams

both eyes were normal in all respects, the excursions of each separately were perfect and all the associated movements good. She declared that with the right eye she saw two distinct images of a pencil held at twenty inches, separated by an interval of some inches and on the same plane

He further adds that he has since seen a little boy with a high degree of myopia who claimed to be the It is definitely subject of the same phenomenon stated, however, that this phenomenon was observed in the right eye only when the left is closed No statement is made, however, as to whether the closure of the non-affected eye in the woman's case was necessary to develop the phenomenon said to have perceived images of double the number of small objects, such as coins that were placed before him, only, however, when the left eye was closed Mr Adams, erroneously I think, supposed that with a prism placed base upwards or downwards before the non-affected eye the boy should have, if he were not simulating, seen three objects instead of two He sums up his remarks by saying that,

Up to the present time (1881) he had never met with a case in which uniocular diplopia, in an eye that was physically perfect, was alleged to exist except under circumstances where there was strong ground for doubting the validity of the patient's state ments.

It would have been pertinent to have asked if Mr Adams had ever before seen a case in which uniocular diplopia was claimed without lesion of the affected eye. He further states that after the receipt of the claimed damages she speedily recovered, but the statement is too indefinite to be of any scientific value. He does not say that he saw and examined who woman, nor does he refer to any one else who

At the same meeting of the Society, Dr O M

Ord narrated in full two cases of uniocular diplopia The one case, a man of 28, may be subject to a certain amount of doubt, and apart from other cases would be of but small value But in consequence of the agreement of this case in certain particulars with other cases in which there can scarcely exist a justi-blood-clot from the ventricle fiable scepticism it is not without value for com-

In neither of the cases referred to by Mr Adams is any mention made of external paralysis, in fact, we are assured in the one case that it did not exist, although according to the woman's claims it had existed and her statements coincide with the observations of others in later cases, and in the other we are justified in assuming that it did not exist at the time of ob-

In the first case mentioned by Dr Ord we have the existence of paralysis or paresis of the external recti distinctly stated There is in this case no mention made of the condition of the iris, although in all probability the pupil was dilated We are led to infer, although it is not stated in so many words, that when both eyes were used he was the subject of ordinary diplopia arising from the feeble or paralyzed condition of the external recti, but no direct statement is made that he saw quadruple images You will remember that says an important peculiarity the closure of the non-affected eye in the case of the boy referred to by Mr Adams was necessary to the development of the phenomenon

The second case reported by Dr. Ord was a school boy admitted to St Thomas' Hospital September 3, 1879, 13 years of age And strange to say, the preliminary symptoms are in some respects very similar to the first case referred to by Mr Adams The boy it is true had an epileptic fit He was quite uncon-No general paralysis followed, but he remained drowsy, and for four days had constant vomiting, and both external recri acted imperfectly. There is no note made that the boy ever saw four images when both eyes were open, and there is no statement The movements of the eyes caused that he did not pain and the pupils were widely dilated Mr Nettleship, of St Thomas' Hospital, also examined this boy and says

I began by simply disbelieving the boy's statement, but re peated and varied trials by others as well as myself, left little doubts that at any rate the boy was sincere in his statements

It will thus be recognized that the phenomenon, if it exists, is an unusually rare one and that it devolves upon any one who presents a case to detail the most

minute particulars

This boy was again, later, admitted to the hospital, and was under Mr MacCormac's care for an abscess on the back of the neck Nothing was then known of his previous history He died quite suddenly Nov 20, 1880 The post-mortem examination revealed in the right cerebral hemisphere, in the normal position of the right lateral ventricle, an old blood clot, having a slight attachment at its lower surface It was egg shaped, about 21/2 inches long and 1 inch

closed with a continuation of the blood-clot blood clot was practically a tumor, was distinct and separate from the right lateral ventricle, but it had displaced the ventricle considerably to the left, there was a half inch of tissue separating the space of the

At the same meeting Dr John Abercrombie reported a case that was under treatment at the Hospital for Sick Children, Great Ormond Street, in the month of July, 1881 The previous history of two months gives a record of headache, vomiting, peculiarity of speech, loss of power on the right side for two months, squint for three months, had chorea, no rheumatism, no convulsions Mother died of cancer, father said to have fits One more child of the family "healthy '

The interesting feature for the present study is the existence when admitted to the hospital of paralysis of the right external rectus, slight internal strabismus of the right eye, no ptosis

Sees double with both eyes and also when right eye alone is used. The false image is always above and to the left of the

No mention made of the condition of the pupils Optic discs obscure, right paler than left, veins in This is both eyes turgid and tortuous Dr Abercrombie

> During the next few days she was repeatedly examined with regard to diplopia, but the result was always the same, viz when the left eye was closed her sight was normal

> July 28, unconsciousness developed, slight convulsions, pulse very frequent, breathing irregular, eyes fixed, staring pupils, moderately dilated—death

> The autopsy is so significant and the publication in which it appears so little circulated that I give it verbatım

> Autopsy 161/2 hours after death Body weighed 441/2 pounds Rigor mortis marked Calvaria and dura mater natural Con volutions flattened, especially in the right posterior region Surface of brain dry and sticky, the two hemispheres adhere to each other, corpus callosum arched Pia mater at base rendered opaque by recent exudation of greenish lymph, a thin layer of which envelops pons Varolii, and causes gluing together of me dulla oblongata and cerebellum The exudation of lymph ex tends into each Sylvian fissure

On cutting into the right hemisphere the white matter in the region of the temporo sphenoidal and occipital lobes is found to be broken down and a large abscess cavity takes its place con taining some ounces of laudable pus, the descending cornu of the lateral ventricle is filled with pus and leads directly into this abscess cavity, the lateral ventricles otherwise are dilated and

filled with a thin slightly turbed fluid

Left hemisphere, cerebellum, pons Varolii and medulla ob longata, natural, left optic disc swollen, margins ill defined. Both lungs show slight hypostatic congestion. A little thickening of mitral valve. Alimentary canal, liver, spleen and kidneys normal. Some of the mesenteric glands a little enlarged and cascous.

Dr Abercrombie adds that there is not the least reason to suspect this child of malingering examined on different occasions without anything occurring to lead us to doubt her veracity I think, therefore, we may accept it as a fact that she had double vision with the right eye

In May, 1884, Mr Marcus Gunn and Dr J Ander-A small aneurism the size of a pea was found son again brought the subject before the Ophthalmo-1/2 of an inch below the blood-clot. The blood vessel logical Society of Great Britain, with the presentation connected with the blood-clot, but the lumen was of another case, and on the same occasion Dr

Brailey and Messrs Juler and Nettleship referred in brief to the cases under their care

The case reported by Mr Marcus Gunn and Dr Anderson was a painter, at 34 years There was paresis of the left external rectus, there was the usual homony mous diplopia of abducens paralysis, but also double images with the left eye when the right eye l'ension in both eyes normal, pupils unequal, left larger, both acted to light and accommo-On looking upward the right globe made a normally on accommodation slight excursion inward on its way, and when he looked to the left his right eye was directed very eye On examining her the first time, suspecting some slightly upward as well as to the left spects the movements of the eye were normal There left eye, I asked her if she ever saw two objects in was no nystagmus was normal-nothing visibly wrong in the cornea, aqueous, 11.5, lens, vitreous, or fundus Examination her statements revealed the diplopia to exist over the left half of the field of vision and also over the upper part of the right half, the images got farther apart as the object It was not possible to obtain neared the periphery the perception of three images by the aid of prisms This patient was also examined by Dr Nettleship There was no reason to suspect the patient of simulation

A detailed history of this case is given in the re-It involves so many nervous lesions that, although syphilis was denied on the part of the patient, and no demonstration of lesion could be made, he was subjected to anti-syphilitic treatment, and so far improved that the diplopia and the paralysis of the external rectus disappeared He was still occasionally subject to attacks of unconsciousness, which were called "fits"

The cases of Mr Nettleship, Mr Juler and Dr Brailley were all associated with paresis of the external rectus and dilatation of the pupil

I will now give the details of a case at present under my observation which gave rise to my presen-

tation of the subject

Mary R, 9 years, orphan, no family history obtain-When she was brought to me her face presented an appearance of great distress, a suppliant Appression, her step was cautious, as though afraid of jarring her head. The left eye was kept partially closed, not from ptosis, but from the action of the orbic- lation would give 450 ularis muscle She complained of severe pain in the oration of the girl's veracity, as the discrepancy could infra-orbital region, greatly aggravated on pressure over the infra-orbital foramen. There was increased pain on even medium movements of the eye, so much so that she would move the head rather than the eye The pain, apart from the infra-orbital region, was located rather in the region of the external rectus, and the position of the pulley of the superior oblique There was no paralysis of any of the muscles demonstrable, and even paresis was very questionable When the eyes were directed upward the left eye turned inward and the effort was associated with great indicative of a pain in the muscles, developed by an non was not noted before the influence of the atropia. effort at contraction. There was a headache which It was not definitely noted that it did not exist, but she said came on every other day. There had been I think I should have noted the fact when measuring and there was no other endered. If and there was no other evidence of any malarial the distances of the extra images from the object, if affection

There was a very slight amount of conjunctivitis of the left eye only, no blepharitis, no other external lesion; cornea, aqueous, iris, lens, and capsule, vitreous and fundus were all normal, and there was no detach There had been no complaint ment of the retina made about the right eye, nor did it present any lesion

V with both eyes together and each eye separately, 76, N V S o 6 Pupils normal in every respect, contracts quickly under the influence of light, and

She persistently claims double vision with the left In other re- difficulty in the form of paresis of the muscles of the In other respects the left eye stead of one "With this eye I do," she said, pointing to the left Quite skeptical, I proceeded to examine

When a probe was held vertically before her at a distance of 50 cm she said she saw two, the extra image being projected toward the median line, and a little less clear She pointed to its location definitely When, however, the probe is held in a horizontal posi tion, she located the extra image as above the object The double images do not change their relative distances when moved toward the nasal or temporal sides, nor when the object is moved up or down, only the observation is less satisfactory on account of the discomfort associated with the efforts at movement

However the experiment was varied, she invan ably gave evidence of double vision with one eye When one, two, or three coins were placed before

her, she saw two, four, or six

It occurred to me to measure the relative distance of the extra image when looking at a near object and one that was more remote Of course such a calcu lation would be a good check on the accuracy of her The principle involved being the distance answer of the extra image from the object at one metre should vary directly as the distance of the extra One measurement which I image at six metres made before using atropine gave me a displacement of the extra image to the nasal half of visual field of 075 millimetres at a distance of one metre, and at six metres the displacement, according to her location, The theoretical distance on calcu 400 millimetres This I considered a corrob well be referred to maccuracy of my crude measure It would have been impossible for a child of 9 years to have calculated so near in the absence of some actual sensation similar to what she claimed

Atropine was applied to the eye, and observations were made two days later when the eye was fully atrophized, the pupils dilated ad maximum, and the accommodation completely mactive answers were given to the same questions, only now she located the extra image not only in the nasal and upper half of the field of vision, but as quite a good deal nearer to her than the object

The vision of the left eye, under the influence of atropia, required a lens S+r D to restore the visual acuity that she had before, showing a slight amount of latent hypermetropia. With the S+1 oo D, however, vision was 6 as before No satisfactory explanation was obtained relative to the deficiency of visual acuity, whether it might be referred to retinal asthenopia or cortical asthenia

The exact displacement of the extra image at one metre during the influence of the atropia was difficult because of the above-mentioned fact that the extra image was nearer to the eye than the object, but approximate measurements gave the distance at one metre to be 65 millimetres and at six metres the distance of the extra image was claimed to be 330 Theoretical calculation would have It will be remembered that under given 300 mm atropia the extra image seemed less distant than the actual object when near objects were under observation, but the phenomenon did not exist when looking at an object at a distance of six metres occur to me to inquire at what distance this phenomenon ceased to be observable

Pursuing investigations further I found the girl to be completely red blind She had no conception of any difference between greens and greys, purple, blue and violet she put together as similar colors

The observations were made at intervals between November 12, 1887, and December 4, 1887 December 4, when in church, she felt that she could neither speak nor breathe, and then she was uncon-Convulsions followed which were said by the Sisters to have lasted four hours After a period of consciousness the convulsions were renewed the same night and said to have continued for a similar After this she felt pain all over the body Confined to the bed December 8, at a consultation with Dr D W Brower, Professor of Nervous and Mental Diseases, at the Woman's College, the double vision with one eye was demonstrated 13, has been frequently delirious since last record, cannot keep anything on the stomach When delinous complains of pain on the top of the head Buries her head as much as possible in the pillows has scarcely varied from the normal December 15, has been very restless-slapped and tore the hair of her little attendart All at once she became better She slept well, complained of no pain, and ate her food, and the vomiting ceased For the first time since she has been under my observation she can now look up without experiencing pain mydriasis, no lack of accommodation, and no paralysis or paresis of the external ocular muscles

She still sees double with the two eyes open and with the left eye alone, the false image referred to the same position whether the right eye is open or closed It is always in the nasal and upper half of the visual I could not get her to acknowledge any inclination of the images

December 23, she left the institution in charge of the Sisters, and the Sister in charge reported she mentally

As she did not return to school, January 19, 1888 I visited her at home I found her afflicted with abscesses all over her body, some under the arms and on the forearm The left eye was giving her no pain, but the double images were present, and a pain which she said was similar to the pain which she experienced in the left was appearing in the right eye

I do not expect to see her again, I close the report The etiology, pathology and location of the cerebral lesion are all involved in so much obscurity

that I shall add only a few words

The similarity of the main features of the case to the two cases above referred to made me suspect from the first time I saw the child the existence of either brain tumor, or abscess The location of the tumor or abscess, simply from the two autopsies referred to above, I referred to the right cerebral hemisphere, in such a position as to encroach on the lateral ventricle I have no theory whatever to present relative to the possibility of double images under the circumstances The development of convulsions and their persistence at intervals with the associated vomiting strengthened that opinion The increased severity of the symptoms on the 14th, and the sudden improvement, made me suspect an abscess and its rupture into the third ventricle The development of abscesses over the body in about two weeks after the sudden improvement, made me suspect that these abscesses were of a metastatic character As to the character of the primary abscess, I have not sufficient data to justify any conclusion, and the want of education on the part of the person in charge of her precludes investigation

APEX EXPANSION VERSUS PURE AIR IN PULMO-NARY CONSUMPTION

December Read before the Philadelphia County Medical Society Febru ary 22, 1888

> BY THOMAS J MAYS, M D, OF PHILADELPHIA

Next to the tubercle bacıllus, impure air stands Pulse has varied from 60 to 75 and the temperature most prominent among the many agencies which have been assigned as the causes of pulmonary consumption Innumerable plans and methods have been devised and proposed for improving the ventilation of our dwellings, hospitals and workshops, volumes upon volumes have been written on the ill effects of breathing vitiated air, and the immaculate freshness of the country and mountain air has come to be universally regarded as a certain guarantee against pulmonary consumption These, like many other popular notions, contain a germ of truth, but actually are delusive, masmuch as they exaggerate the effects of a small evil, and afford a false sense of security against the real source of danger in the production of this disease This we shall endeavor to show in the following pages

At the very outset we desire it to be well understood that we do not in the least underrate the value seemed well as ever but less active and less capable of fresh, wholesome air in the prevention and treatment of pulmonary consumption, and while it is probably true that on the whole country people en-10y greater immunity from this disease than city people—though this is not proven, on account of a lack of adequate statistics—yet we are convinced that the purity of the atmosphere plays a very small part in bringing about this probable result If we are permitted to make a homely, hypothetical proposition, we will state that if two individuals who respire the same quantity of air, and who are equally well | known among any native people who live more than off so far as heredity, food, clothing, warmth, comfort, etc, are concerned, were both enjoined to maintain a sedentary and a stooped position of their bodies for an unlimited period, one inside of a house and the other outside in the open air, we have no reason for believing that the one inside will fall a victim to this disease sooner than the one on the outside

If it were true that this disease is the result of breathing a vitiated and impure atmosphere, how can we account for the fact that the inhabitants of Iceland, Greenland, Lapland, and of other cold countries of the north, who live in dwellings which are notoriously wanting in ventilation, are practically exempt from this disease? Of the Icelanders, Mr Warnford Lock, who is very familiar with these people, says that their life is

"one long exposure to the elements, and during the night they live in dwellings devoid of ventilation, and which, if not buried beneath the earth, are built of turf and often become grass grown. A very bad feature being the excessive stuffiness of the common living and sleeping room, when, owing to the ab sence of fires, the greatest possible crowding and plugging are necessary in order to maintain a tolerable degree of warmth "

And yet Dr Cullimore," from whose work the above quotation is taken, says (p 73)

"that consumption in Iceland is never indigenous, but is al ways, when it does occur, imported from abroad and but sel dom extends to the second native generation "

On the other hand, it may be stated that the people of the tropical regions of the globe who enjoy an uninterrupted reveling in pure, fresh air, both day and night, winter and summer, are by no means free The only difference, from pulmonary consumption so far as the physical life of these two classes of people is concerned, is that the warm climate, which produces such a luxurious atmosphere, also creates a tendency to physiological sluggishness and an indisposition toward physical exertion among its inhabitants, while the people of the cold and rigorous north are compelled to maintain the warmth and vitality of their bodies in great part, by day, through physical exercise, of which their occupations of hunting, fishing, herding, etc , give them a full share is also well known that miners and laborers employed in coal mines, who continually respire an atmosphere loaded with impurities, and damp and musty, suffer but very little from this disease

One fact which lends color to the belief that pure air is such an essential element in limiting the ravages of consumption, is that those who occupy elevated or mountainous regions are less liable to this disease than those who live near the sea level Thus Fuchs shows from extensive data that

"at Marseilles, on the seaboard, the mortality from this dis case is 25 per cent, at Oldenburgh, eighty feet above the level of the sea, it is 30 per cent, at Hamburg, forty eight feet above the sea it is 23 per cent, while at Eschevege, four hundred and ninety six feet above the sea level, it is only 12 per cent, and at Brotterode, eighteen hundred feet above the sea, it is but 0 9 per cent "

Carrying this line of observation further, it ap pears very probable that consumption is almost un 6000 feet above the level of the sea

Now that which concerns us here chiefly is the reason why mountain climates are, as a rule, so free from pulmonary consumption Is it because the atmosphere is pure and free from septic germs? This is hardly possible, for if it were true that the asepho condition of the air played any very prominent part, why should the Icelanders, who nightly reek in a most filthy atmosphere, or the dwellers along the Nile, who, according to Mr B Phillips, live "in huts where the pure air has neither ingress nor egress, ex cept through a small hole near the ground," or the coal miners, who continually respire a foul and poisonous atmosphere, all be comparatively free from this disease? Is it due to the general absence of humid ity? We think not, for Bogota, the capital of the United States of Colombia, located on the Andes, near the equator, and at an elevation of over 9000 feet, is said to be entirely exempt from this disease, although dampness prevails to quite a large extent We think there is much reason for believing that it is principally, if not entirely, on account of the at tenuated condition of the atmosphere, and shall, therefore, at once proceed to consider the physiolog ical influence of high altitudes on the human body

It is estimated by Dr Denison that at an eleva tion of 6000 feet the surface of the body is relieved of nearly 7000 pounds pressure When such an en ormous weight is lifted from the body it is quite evident that its interior must also be markedly af fected—the pulse is accelerated from fifteen to twenty beats per minute, the respiration is quickened from ten to fifteen breaths per minute, evaporation from the skin and lungs is increased, and the amount of These are some of the imme urine is diminished Protracted residence in such a high diate effects The Quichua region enlarges the chest capacity Indians, who dwell on the elevated table lands of Peru, have enormous-sized chests, containing capa cious lungs with large air cells The Mexican In cious lungs with large air cells dians possess chests which are out of proportion to the sizes of the individuals Dr Denison says that children born in the Rocky Mountains have chests of unusually large capacity, and M Jaccoud states that at St Moritz the respirations are not only more frequent, but fuller

The reason why the number of respirations in crease while ascending a high elevation becomes clear when we take into consideration the fact that at the sea level a cubic foot of dry air contains about 130 grains of oxygen, while at an elevation of 6000 feet it contains only about 106 grains—nearly 25 per cent less than the body is accustomed to breathe at or near the seaboard—therefore, in order to sup ply the wonted amount of oxygen to the body, the

¹ The Home of the Eddas S Low, 1879
2 Consumption as a Contagious Disease Ballière, Tindal & Cox, 1880

respirations must either increase in number or in ex-From all accounts it is very probable that respiration becomes accelerated only during the early period of exposure to such an attenuated atmosphere, and that subsequently this function becomes slow again because the air penetrates more deeply and completely into lung tissue but little util-1zed before

That man does not suffer under such a deprivation of oxygen is evident from what we know to be true of his lung capacity under ordinary conditions of Prof Mosso has recently proven experimentally that man possesses a lung capacity which is nearly one-fourth larger than the actual necessities of life at the sea level demand, hence by employing his whole lung capacity he can extract a sufficient amount of oxygen from this attenuated atmosphere without difficulty And herein lies the secret why so many consumptives and others with weak lungs, denve such a great benefit when they resort to a mountain climate It may be trite, but it is nevertheless true, that all consumption practically begins at the lung apices, because these parts are habitually They are mactive because, in the first place, the bronchial tubes are so arranged that they conduct the air with greater facility to the base than to the apex of a lung, and, in the second place, because the lung is larger than necessary, hence the base, which is filled most readily, is filled first, and the apex, if at all, toward the end of inspiration The apices, therefore, become the superfluous parts of the respiratory organs It is quite different, however, when the body is immersed in a highly attenu ated atmosphere Every available space in the chest is now brought into requisition to furnish the needed amount of oxygen, the apices are called out of their lethargic state, and the alveoli are inflated, and if the infiltrated areas are not dispersed the surrounding alveoli are kept permeable, and so the disease is, at least, limited and called into abeyance

This statement is corroborated by those who have pulmonary consumption Thus Ruedi⁸ reports "that of 600 consumptives under his care at Davos, expansion of the thorax took place in no less than 584" Dr Denison says "the increased circumference of the chests of consumptives after undergoing the high altitude treatment is shown in many of Prof Weber's, as well as in my own, cases " Dr Lindsay, in the work already quoted, states (p 32) that

Davos does not cure consumption by its sunshine, or the pur ity and dryness of its air (although these conditions undoubtedly cooperate in the beneficial effect), but mainly by the rarefaction of its air, which stimulates respiratory activity, promotes healthy expansion and soundness of tissue in the lungs, and hence aids them to resist the spread of morbid deposits."

So much then, for the immunity which is afforded by mountain climates, but that which is of still greater interest to us is the fact that those who follow active employment are less liable to this disease than those who pursue sedentary and quiet occupations Thus, M Lombard found

"in Paris, Geneva, Vienna and Hamburg, that there are a

greater number of persons leading a sedentary life afflicted with phthisis than of those leading an active life, in the proportion of 141 to 89 In the Brompton Hospital the relative liability was found to be 63 per cent of indoor males to 30 per cent of outdoor, and all the consumptive females followed indoor occu pations Dr Guy found, in the close workshops of a printing establishment, the compositors, whose employment is sedentary, fell victims to phthisis in the proportion of 44 per cent to 31½ per cent of the pressmen, who, although breathing the same air and in every other respect subject to the same habits of life, differ only in the active bodily exercise which the press imposes on them, and among the same class of operatives the deaths from the same cause did not exceed 25 per cent in those who use exercise in the open air " (Ancell)

There can be no doubt, too, that those of our Indians who are still allowed to obey their roaming instincts of hunting and of fishing, or to follow their vocation of farming, which a number have, owe their immunity from this disease, which we know they possess, in great part if not entirely to the physical exercise which they obtain in this manner, while those who are subjected to the idle and improvident reservation life die rapidly from it, principally because they are deprived of their wonted exercise This is of special interest to us here, because it has such a direct bearing on the main point at issue the former class of Indians, like the Pimas, for example, who may be called wild, although they are agricultural in their habits, are living in half underground huts with very little or no ventilation, yet, from all accounts, consumption is an exceedingly rare disease among them Thus far we have seen that, on the whole, those

who occupy elevated habitations, as well as those

who follow active exercise, are more exempt from the disease under consideration than those who live near the sea level or those who live a life of quietude In connection with this we will consider the influence of physical exercise on the lungs, and endeavor to ascertain how it affords protection against consump-During physical exercise more oxygen is consumed by the muscles, and more blood and air circulate through the lungs than during rest had large experience in the climatic treatment of much more air enters the lungs during activity than during rest can easily be estimated when it is known that during inactivity a man breathes 480 cubic inches of air per minute, and while walking at the rate of four miles per hour, or while tramping a treadmill, he breathes 2400 cubic inches, and if he walks at the rate of six miles an hour he takes in 3260 cubic inches of air per minute The difference between 480 and 2400 cubic inches of air-capacity shows that during the exercise of walking even at the rate of four miles per hour, five times more lung surface is thrown into action than during rest, which proves very conclusively that bodily activity possesses a marked influence in determining the degree of lung expansion, and that under such conditions regions of lung will be called into service which are never fully reached by air during bodily rest

This is in entire accord with what practically exists Thus Darwins says that the lungs in improved breeds of cattle, which naturally take little exercise and are domiciled much of the time, "are found to be considerably reduced in size when compared with those possessed by animals having perfect liberty," and

² Climatic Treatment of Consumption B, Dr J A Lindsay p 6-⁴ Rocky Mountain Health Resorts p 85

Waldenburg' states that the vital lung capacity is smallest in persons who lead sedentary lives, such as professional men, students, clerks, etc, and is greatest in those who follow active outdoor occupations, such as sulors, recruits, etc Chassagne and Dally, in their joint work on the "Influence of Gymnastics on the Development of Man," report that at the Military School of Gymnastics of Joinville-le-Pont, out of 401 individuals subjected to gymnastic exer- not from one of permanence, the mountain climate cises for five months, 307, or 76 per cent, showed an is to be preferred increase of an average of 2 5 centimetres in the mammary circumference of the thorax According to must not be overlooked that, on account of its rare Dr Abel, 75 per cent of those who practice gymnastics in Germany experience an increase in the meas-There can be no doubt that | urements of the chest the principal reason why consumption increases with not be denied to physical exercise, although it is the advent of civilization is that everything in civilired life tends to produce physical inertia in our bodies Walking is substituted by riding in carriages and in cars, manual labor is in great part replaced by machinery, active outdoor labor is supplemented ing that it is not so much a question of developing by quiet indoor occupations—in fact, everything the base of the lungs as it is one of expanding the which tends to produce physical activity is ex- apices changed for a life of ease and indolence American Indian, as has already been stated, is less chest capacity than the male, yet, owing to her known to be comparatively free from the disease in increased costal expansion, which has been culti his wild state, but as soon as he acquires the habits and customs of civilized life he becomes its victim

In converging the two lines of reasoning which male? have been thus far developed in this paper, it appears that the immunity from consumption which is parative effects of mountain climate and of physical established by residing in a mountain climate, and by practicing physical exercise, is chiefly brought and it now remains to be shown how the effects of about in the same manner, viz by increasing the capacity of the chest And from a practical point of view it is of some moment to know whether the former has more weight in bringing about such restoration than the latter-or, in other words, whether those who live in high altitudes continue to enjoy this exemption if they refrain from active physical exercise and take up a sedentary occupation in such From recent inquiry into this subject we are inclined to believe, at least so far as the Rocky Mountain climate is concerned, that as soon as outdoor pursuits are exchanged for sedentary indoor occupations, consumption increases in frequency It 15, therefore, quite certain that physiological exercise plays a more important part in the problem of proposition and cure of consumption than a residence proposition and cure of consumption than a residence intervals.

Bodily Exercise—The power of walking is common to most people, and its influence on the lungs, as we have seen, is very marked. It is regarded of great service even by those who exclusively advocate the utility of high altitude treatment. Dr. Brehmer, of the utility of high altitude treatment. cise plays a more important part in the problem of fer but venountain climate, for it is a common for but venountain climate, for it is a common for but venountain climate, for it is a common for but venountain climate, for it is a common for but venountain climate, for it is a common for but venountain climate, for it is a common for but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the but venountain climate, for it is a common for the utility of high altitude treatment. Dr Brehmer, of Gorbersdorf, according to Schreiber, was the first to prescribe, for consumptives, walking up a gradual ascent. the sea level is always regarded as perilous Such hour, either on the level or on a slight upward grade, insequences are in perfect harmony with what one is of immense advantage to the invalid ould be led to apprehend from a knowledge of the dancing, skipping rope, (especially when the rope is lysiological factors involved in the restoration of swing backward), bowling, etc, are to be highly These factors are entirely local, and recommended

their influence does not extend very far beyond their immediate dominion This objection does not hold good in regard to physical exercise One thing may be said, however, in favor of mountain climates which is not true of physical exercise, viz it produces its beneficial results without conscious effort on the part of the individual, therefore, when the remedy is viewed from a standpoint of ease and comfort, and

In discussing the influence of mountain climate it faction, it increases the circulatory and cellular activity of the body, and in this way undoubtedly aids the process of nutrition, yet even this influence can brought about in a more direct and positive manner

While increased chest capacity is, therefore, the great desideratum in preventing and treating consumption, we have the strongest evidence for believ This is well shown by the fact that the civ-The lilized female, although she has on the whole much vated through the protracted influence of tight lacing, she is less liable to pulmonary consumption than the

Pulmonary Gymnastics —Such, then, are the com exercise in the treatment of pulmonary consumption, the latter can be obtained without resorting to those Reference has already been made to of the former the fact that muscular effort increases respiratory motion, and in taking up the question of pulmonary gymnastics, it is not our purpose to discuss those exercises only which have a direct influence on the chest capacity, but also those which, through the body, have an indirect influence on the pulmonary organs. In all exercises it is very important that none should be carried to the extent of decided fa tigue, and that, whenever possible, the body and head should be kept erect, the shoulders thrown back and the lungs thoroughly filled with each breath, that breathing should only take place through the nose, and that sufficient food is taken during the

Whatever the mode of exercise may

⁶Animals and Plants vol 11, p 361
⁶Pneumatische Behandlung Respr u Circul Krankheiten, p 119
⁷Female Dress as a Determining Factor in Pulmonary Consump tion Thomas J Mays, Med News, January 7, 1888

be, it must be performed under as little compulsion One reason why the above named exercises are so conducive to health consists in the fact that the excitement which they induce is so attractive that the consciousness of muscular effort is

Among the many indoor exercises the following movements are very valuable The arms, being used as levers, are swung backward as far as possible on a level with the shoulders during each inspiration, and brought together in front on the same level during each expiration, or the hands are brought together above the head while inspiring, and gradually brought down alongside the body while expir-When a deep inspiration is taken in accordance with either plan and held until the arms are gradually moved forward or downward, or even longer, the process of chest expansion is materially enhanced

Another very effective exercise is to take a deep inspiration, and during expiration only the patient, in a loud voice, will count as long as possible male person with a good chest capacity can count up to sixty or seventy, while in a female with ordinary lungs this power is somewhat reduced tice of this sort will gradually develop the chest, and the increased ability to count is a measure of the improvement going on within the thorax

Many of these movements may have their effects greatly enhanced by the use of dumb bells, chest weights, etc, which are made especially for the

Compressed and Rarefied Air —The breathing of compressed and rarefied air is attracting wide attention at the present time in connection with pulmonary consumption, and is another most useful method whereby the chest capacity can be markedly Nearly four years ago Dr Cohen, the *improved* honored President of our Society, advocated the substitution of compressed and rarefied air for a change of climate, in a paper which he read before the American Climatological Association Here he says

"In many cases fully as much good can be secured by this treatment as by change of climate, and in a few much more, though, in the vast majority of cases in which change of climate is advisable, it is but a poor substitute "

There can be no doubt that compressed and rarefied air is inadequate when used alone in many cases, but when combined with pulmonary gymnastics and other judicious treatment, we are not sure that the results obtained are inferior to those which are derived from climatic treatment Recent experience has shown us that when consumptives, who had spent one or two winters on the Rocky Mountains, or on the Pacific Slope, without benefit, were subjected to the use of compressed and rarefied air in association with other pulmonary exercises, such as are above described, their improvement became marked and decided On the whole, our experience with the air treatment, combined with pulmonary gymnastics, has been very favorable, and we think that this is in consonance with the observations of Thus the late Professor Flint, in his work on Phthisis, says (p 406)

ence, as compared with the hygienic measures available at home" changes of climate have in a marked degree a beneficial influ-

We believe, however, that, as a rule, these measures are applied too infrequently to be of the greatest service, and, therefore, insist that the pulmonary gymnastics be repeated every hour and a half during the day—the first thing in the morning and the last thing at night—and for from fifteen to twenty minutes at each time, and that the air inhalations be given at first twice, and in the course of two or three weeks gradually increased to four or five times a day, and even oftener It is very true that this method of treatment involves more labor and perseverance on the part of the patient than is required in a high mountain climate, but then it is a question whether the patient is not more than compensated by the consciousness that a separation from friends is unnecessary, that the heavy expense, the dangers and discomforts incidental to travel are avoided, and, above all, that the improvement which may take place will be persistent and be practically unaffected by a change of residence

Now, after reviewing the whole subject, we are driven to the conclusion that the line of immunity from consumption, which, in the early history of our country, was located at the Atlantic seaboard, and which has gradually receded westward with the tide of civilization, until at present it has reached the latitude of Colorado, will not stop in its course until it touches the shores of the Pacific, that the question of curing the disease does not depend on the purity or freshness of the air, or upon the number of bacilli which the atmosphere may contain, or upon the amount of oxygen which may be introduced into the body-for these are all secondary considerations, but it is simply a mechanical question—a question as to the best mode of expanding the lungs, and especially the apices of our round-shouldered and flatchested patients, of removing the infiltrated products already existing, and of enhancing the constitutional

resistance

MEDICAL PROGRESS.

ANATOMY AND PHYSIOLOGY OF THE PHRENIC NERVE -MR W W WAGSTAFFE has the following note in St Thomas's Hosp Reports, vol xvi, 1886

During the course of teaching and examining I have been struck with the absence from most, if not all, of our text-books, of any notice or explanation of an important fact which appears obvious anatomically—the peculiar relation of the phrenic nerve to the anterior scalenus muscle Our most generally used anatomical works ignore the fact that in passing over this muscle the phrenic nerve sometimes gives branches to it This I have traced in several cases, but it is no doubt more usual for the branch of supply to the muscle to come from the fourth cervical nerve close to the origin of the main root of the But whichever arrangement exists, the as-"It does not appear, from the analysis of my cases, that sociation of either the trunk or the root of the phren-

ic with the nerve-supply to the anterior scalenus is ure of success, but in all of them still earlier interthe fact I wish to emphasize, and the course of the ference would have been better surgery and more nerve over the muscle must also in itself be looked advantageous to the patient upon as a matter of interest and importance Those to a rule that an operation should be done at a given few anatomical authorities who mention the fact of time from the onset of an attack branches to the anterior scalenus sometimes coming is not appreciated by the physician in attendance, from the phrenic, either entirely omit a reference to or the friends object, or some variation in the sympits obvious physiological use as a motor nerve to this toms leads to the hope that medical measures may muscle, or lose sight of what appears an important suffice physiological connection between the diaphragm and finement in diagnosis, such as the location of the the anterior scalenus in respiration

Even in standard physiological works I do not find ture a satisfactory reference to this fact Professor Michael Foster alone among English authorities gives arrive at valuable conclusions in these respects, but any prominence to the special value of the scaleni I think the deciding of the main question, Does inin the mechanism of respiration, but even in his admirable work the meaning of the relation of the conclusion once reached, medical measures may be phrenic to the two extremities of the thorax is not resorted to satisfactorily enunciated And in speaking of the effects of the division of the phrenic (in the rabbit) reference is only made to its influence on the dia- to acute obstructions ing a point which would be interesting to notice, and this is how far the relationship of the phrenic to the anterior scalenus is common to animals having thoracic respiration

Noting, then, that the phrenic in passing over the anterior scalenus may supply it with branches, and that its final distribution is to the diaphragm, we have, it seems to me, an important anatomical fact indicating the simultaneous action of the upper and large enough to admit the hand should be made, and lower ends of the respiratory apparatus—a mechanism which the ordinary bellows or concertina may roughly exemplify The scalenus would fix and raise the first rib, from which the intercostals would work, probably external and internal, thus acting as elevators of the ribs and increasing the lateral capacity of the chest, while the diaphragm of course increases the longitudinal capacity 1

The course taken by the phrenic is suggestive of its physiological function on the muscles above indicated, and it would be of interest and value to notice the effect of injury or disease upon the phrenic between these two endings, such cases, however, are Some interesting cases are to be not easy to find found in Le Gros Clark's paper just referred to, but in these the whole of the phrenic has been paralyzed from injury to the cord, and we cannot distinguish the function of the phrenic as to its double supply

Henle notices one case, but one only, of branches coming from the phrenic to the anterior scalenus, and this case is given on the authority of Luschka I shall be satisfied if this note calls attention to the of Boston, says that he has laid down the following fact, and suggests a satisfactory physiological ex-{principles for his own guidance planation

LAPAROTOMY FOR ACUTE INTESTINAL OBSTRUC TION -In the Medical Record, of February 25, 1888, DR W T BULL records five cases of intestinal obtories show that the operations were done as early any tendency to again prolapse. If it does so, it is struction operated on, with two deaths as consent could be obtained, and with a fair meas-

It is difficult to adhere Either the danger Much valuable time is lost in efforts at reseat of obstruction and the determination of its na-I do not mean to speak lightly of the informa tion we possess, which will sometimes enable us to testinal obstruction exist? is more important. This If they fail to relieve at the end of from twenty-four to forty eight hours, the operation should be performed In this I refer, as a matter of course, In chronic cases, like the I have not the means by me of determin-last two narrated, it is proper to delay longer persistence of pain which requires morphine for its relief, the continuance of vomiting, the failure to provoke a movement by several rectal enemata, aided by mild aperients, these symptoms, with or without commencing tympanites and without fever, should invite the attention of the surgeon, and demand operative interference unless promptly re-The operation decided upon, an incision the presenting intestine pushed away to permit in spection of the rectum, cæcum, and sigmoid flexure Then bands may be felt for, or empty loops of intestine, and this failing to discover the lesion, the gut may be searched, while still inside the belly, for congested or distended portions This can be done rapidly, if the edges of the abdominal wound be Removal of the small intestine strongly retracted from the cavity, or "eventration, "which has been advocated by Kummell, seems to me a very serious It has, in the instances where I have done it for gunshot wound, invariably produced great shock It might seem proper if the intestine were not heavy from congestion and enlarged by distention, but when such a condition exists, I think enterotomy would be preferable to "eventration," or to the emptying of the gut by incision, as proposed by Greig Smith

> DANGERS OF SIMPLE EXTRACTION OF CATARACT -In an article on this subject DR HASKETT DERBY,

r He would reserve simple extraction for those cases in which the cataract is ripe, the nucleus large, the patient tranquil and amenable to discipline

2 After the operation, the application of the bandage should be slightly delayed, the object being to ascertain whether the iris, once replaced, shows to be at one excised

3. Eserine is to be applied directly to the eye immediately after the operation, and dropped in the

¹ Vide Le Gros Clark on the "Mechanism of Respiration," Proc Royal Soc, 1872, a paper too much overlooked

(as recommended by Schweigger) for the three following days

4 Greater quiet on the part of the patient is to be insisted on than has been the case after the op-

eration of Graefe

5 The eye needs to be inspected much sooner,

certainly by the end of the third day

And even if these or similar rules be followed, I cannot resist the belief that for the average surgeon, and in the present state of our knowledge, simple extraction at the best involves an element of danger that is wanting in the method of Graefe The successful extraction without iridectomy is unquestionably the more brilliant of the two methods, and the patient thus cured a more striking exemplification of A greater familiarity with the new surgical skill operation may cause the risk to assume inconsiderable proportions But some risk is likely to always It is like the old question as to the relative advantages of ether and chloroform the latter easier to transport, pleasanter to take, quicker in its effect, and occasionally, alarming in its consequences -Boston Medical and Surgical Journal, Feb 23, 1888

THE ETIOLOGY OF GASTRIC ULCER -Impressed by the fact that women employed as cooks so frequently suffer from gastric ulcer, Decker (Fort schritte der Med, B v 415) instituted some experiments on the action of hot foods in producing the Two dogs were repeatedly fed through the stomach tube with semi-solid food heated to 120° F The first received nourishment in this way four times, and the other eight times At the autopsy of the first dog the mucous membrane of the stomach ap peared normal in all parts, except at the lesser curvature, where there was situated a hyperæmic spot. about four-tenths of an inch in diameter, caused by and muscular layers

In the second dog there was found a dark red area on the posterior gastric wall, about the size of a quarter of a dollar

gastric ulcer

servations of Ritter are of interest (Zeitsch f kl that gastric ulcer can be produced by violence acting ary, 1888 through the abdominal walls Several such cases have been studied in Leube's clinic, and an autopsy

inner corner of the eye, without separating the lids narcosis was then continued until death resulted The autopsies, revealed regions of hæmorrhage beneath the mucous layer, separating it from the tis-There is no doubt that the gastric sues below juice would have soon produced ulcers at these spots, had the animals been allowed to live

The action of trauma in producing ulcer is probably connected with the quantity and quality of the Then, too, a more chronically gastric secretions acting trauma, such as disturbance of the circulation, plays, perhaps, a more prominent rôle than has been ordinarily supposed, though it is difficult to understand why chlorosis should lead to circulatory disturbance oftener than do pulmonary or cardiac

It seems very probable that the use of the corset is also a frequent factor by pressing the stomach against the vertebral column Thie, combined with the pressure of the food toward the pylorus, and the anæmic condition of the mucous membrane in chlorotic women, may be sufficient to deprive the part of blood to such a degree that the gastric juice begins to act upon it -American Journal of the Medical Sciences, January, 1888

UNEQUAL WIDTH OF THE PUPIL IN INTERNAL DISEASES -DR F PASTKERNATZKY, from observations made at the clinic for diagnosis and general therapeutics of Prof Ischndowsky (Arch Ophth, vol xvi, No 3), gives the following He generally found unequal width of the pupil in those constitutional diseases in which there is a distinct anatomical lesion, generally on one side only (croupous pneumonia, pleuritis, renal colic, affections of the heart and liver) The various diseases may be ranged as follows, as regards the frequency of occurrence of this symptom In croupous pneumonia, inequality of the pupils occurs in 85 per cent of all cases, in a hæmorrhagic extravasation between the mucous heart disease and aneurism of the aorta, in 61 per cent, in pleurisy, in 52 per cent, in catarrhal chronic pneumonia, in 38 per cent, in acute rheumatism of the joints, in 25 per cent, in catarrh of The mucous membrane over the respiratory passages, in 25 per cent, in scurvy, it was shrivelled, and resembled felt, and had been in 16 per cent, in typhus fever, in 16 per cent, in somewhat separated from the muscular layer by the febris recurrens, in 15 per cent, in typhoid fever, occurrence of hæmorrhage between them In the 13 per cent In croupous pneumonia the pupil of pyloric region were two typical gastric ulcers, ex- the affected side is larger in the beginning of the tending to the serous layer The author considers process, the maximum of dilatation is reached at the the hæmorrhagic infiltration, the shrinking and eleva- height of the disease Shortly before the crisis, and tion of the mucous membrane, and its final destruc- during the latter, the pupils become equally wide, tion, to be the three phases in the formation of while during convalescence the pupil of the affected side becomes smaller The author believes that the In connection with Decker's experiments the ob- inequality of the pupils in internal disease is a reflex phenomenon in close connection with the process of Med, B 11, H 5, 6, 592) There are a number of disease, the nature of which has not vet been deterclinical observations which render it almost certain mined - Dublin Journal of Medical Science, Janu-

TREATMENT OF ARTICULAR RHEUMATISM—As the of Hofmann's offers additional evidence in the same result of much experience Aufrecht has come to direction Ritter made some experiments on dogs use salicylic acid in acute rheumatism, to the excluto prove that ulcer could actually be brought about sion of other drugs, and with complete success. He in this way The animals received a rather heavy gives the acid in full doses, gr 90 a day for the first blow over the region of the stomach, and chloroform two or three days, and gr 45-60 a day for the following eight or ten days carried out in all cases however, since burning pain gestions occur in the stomach, vomiting, tinnitus aurium, or dyspncea prevented the use of the drug Nor could salıcylate of soda, in corresponding doses, be used in these cases, since it caused the same disagreeable prove the nutrition of the skin, it is desirable that symptoms, and was not so effective in keeping down the processes of waste and repair be carried on with

pain and fever When salol was introduced Aufrecht tried it, and with improvement in some respects. It caused but little local or general disturbance, and its use could be continued as long as desired, one patient took of their functions gr 3500 in doses of gr 90 a day But in acute polyarthritic cases salol was not so effective as salicylic acid, for while the latter generally subdues pain and fever in twenty-four hours, salol requires three or four days, though the pain is greatly amelnorated in a shorter time Still, in consequence of bidding all stimulants, on the ground that they do its many advantages, Aufrecht used salol as routine no good and may do harm In charity practice it treatment until he had a fatal case of acute endocarditis-which he had not met with in 600 cases scribe medicine for patients who are living largely on Since that time he has treated with salicylic acid adopted a mixed treatment Acute cases receive 90 gr of the acid in each of the first two days, and afterwards the same amount of salol, but later, while the patient is still in bed, the salol is reduced to gr 60 a day Since salicylic acid is generally well borne for two days, this method of using the drugs seems worthy of trial as routine practice Of course, if the acid can be taken agreeably it may be continued

Salol is in every way preferable in chronic articular rheumatism, since by its use the dangers of the prolonged use of the acid are avoided, and there is more hope of a permanent cure - Deutsche med

Wochenschrift, Jan 12, 1888

Acetanilide (Antifebrin) in Febrile Diseases DR ADEMSKI (Wratsch, 1887, No 25, quoted by Bull Gen de Therap, January 15, 1888) narrates his experience with acetanilide in various febrile dis-Amongst them were 4 of typhoid, 3 of acute rheumatism, 2 of pleuro-pneumonia, and 1 each of intermittent pleurisy, phthisis, and erysipelas all patients bore the remedy well, and in one case of acute rheumatism a dose of sixty centigrammes (ten grains) brought on symptoms of collapse The tem-A dose of two perature was invariably lowered grains every hour rapidly lowered the fever heat. The pulse is lowered from ten to thirty beats per minute, and the respirations may be brought down Sweating was a confrom twenty-six to fourteen In large doses acetanilide induces stant result hypnotic effects, and in such cases as acute rheumatism and erysipelas, manifests an anodyne action Diuresis was a symptom in the majority of cases The urea was lessened, but the total output of nitrates was increased, the phosphates, the chlorides, and the sulphates were diminished in quantity The diuresis for the most part consisted, therefore, in a mere increase of the urmary water -Am Journal of Med Sciences, March, 1888

STIMULANTS TO BE AVOIDED IN THE TREATMENT OF SKIN DISEASES —In an article on diet in cutane-

This course could not be ous affections, by Dr. G. H. Fox, the following sug One very important point to be considered in preparing a diet list for patients with skin disease is the effect of alcohol, tea, coffee, and tobacco in retarding tissue metamorphosis To im When alcohol or other stimulants out cessation are consumed to any extent, this desirable change or reconstruction of tissue is arrested, and the various organs of the body are impaired in the performance The effect of beer upon an eczema is as marked as it is upon a gonorrhœa. Dr Fox has sometimes thought it better for a patient to drink a whole bottle of whisky than a single glass In cases of pruritus, in private of malt liquor practice, the author has fallen into the habit of forhas often struck him as the height of folly to pre tea and beer, and whose symptoms would speedily disappear under a judicious regulation of diet In deed, it is difficult to appreciate what dietetics will do in the treatment of cutaneous and other diseases unless we move, for the time being, a suspen sion of the Pharmacopæia - Dietetic Gazette, January, 1888

> PENETRATING GUNSHOT WOUNDS OF THE CHEST -DR GOUZIER has published some observations and statistics regarding the penetrating gunshot wounds of the chest occurring in the French expedi tions to Formosa and Tonquin in 1883-85 From his work we gather that such wounds showed a mor tality of ro per cent, which is only about one sixth of that due to similar wounds in recent European Apparently, as he wars and in the American war suggests, the general employment of antiseptic methods was the cause of this great amelioration Chest wounds from revolver balls of seven millime tres in diameter generally proved comparatively Traumatic pleurisy and pneumonia usu ally terminated favorably, but hæmorrhage, empye ma, and compound fractures of the ribs gave much He found that the best prac more serious results tice was not to explore unless it was necessary to extract the ball, and not to attempt extraction unless the ball was just beneath the skin or was setting up In ordinary cases he dangerous complications found the best plan was to close the wound antisep tically, but if there were empyema, to make a coun ter-opening and to wash out and drain the pleural Warm antiseptic baths were also found very cavity useful in Tonquin — Lancet, Jan 7, 1888

> LANOLIN AND BACTERIA —GOTTSTEIN has found by experiment that landlin is not decomposed by the agencies that commonly destroy fatty matters, and that the skin to which landlin has been thor oughly applied is less likely to be invaded by poisonous germs and materials than when lanolin is not applied - Therapeutische Monatshefte, Jan, 1888

ACTION OF INDUCTION CURRENTS IN SUBCU TANEOUS INJECTIONS

For many years there has been a good deal written and said as to the best means of using subcutaneously certain drugs, such as quinine, ergotin, arsenic, ether, camphor, preparations of mercury, and others, without having unpleasant local results follow the injections, but no method that has been suggested hitherto has given favorable results cians that have treated syphilis by the subcutaneous use of preparations of mercury know that the chief difficulties and disadvantages of the method lie in the fact that these preparations cause trouble at the site of the injection

A solution of the problem has been recently offered by DR WACHSNER (Die Wirkung des elektrischen Inductionsstromes auf subcutane Einspritzungen, Deutsche medicinische Wochenschrift, No 51, 1887), who proposes to increase the absorptive powers of the tissues by the electric induction current, so that the foreign body will be more quickly removed, and the injected solution act more quickly and with more certainty Careful dissection of the portion of the skin immediately over the subcutaneous cellular tissue shows that there is an apparatus in connection with the cellular tissue that has the power of strengthening the physiological functions of the vessels, and of causing an acceleration of the stream through them This is a muscular apparatus that can be made to contract by an electric irrita-We know that the muscles are motive powers latissimus dorsi

of muscles capable of causing excitation are more energetic and powerful upon the movement of currents in the vessels than its vital contractions When such a muscle is made to contract, it of course becomes shorter and thicker This thickening exerts pressure on the lymph and blood vessels of the skin above the muscle, and these vessels are thereby When relaxation takes emptied of their contents place, there occurs a quick and energetic imbibition, and all the vessels, the cellular tissue, and the muscle become filled, and the structures in the vicinity are thus affected by the movements and changes of the muscle When, therefore, a subcutaneous injection is made, and these muscular contractions are provoked, the foreign body is soon disposed of, and disturbances from it are prevented The return of a portion of the solution to the site of injection is prevented by the valves of the vessels, so that the solution is pressed and carried forward toward the general circulation A proof of this suction-power is shown by electrization of the diaphragm, or phrenic nerve, in cases of asphyxia by chloroform, illuminating gas, drowning, etc., the action of the diaphragm draws air into the lungs

For provoking these muscular contractions the electric induction current is the best means constant current requires a large number of elements, and muscular contractions are provoked only on the opening and closing of the currents, and what is needed in the cases of which we are speaking is that the current oscillations should take place in the smallest periods of time possible periments Wachsner used the Leclanché apparatus, which he considers far preferable to any other bat-For the negative current a small electrode must be used, in order to diminish the resistance A considerably larger electrode must be used for the Direct faradization—faradization positive current of the nerve endings in the muscles—should be prac-In order to bring the current into the neighborhood of the superficial muscular nerves, it is advisable to strengthen the conductive power of the skin, and this is done by moistening the skin immediately before the use of the electric current with a warm salt solution, and by allowing the electrodes to remain for one or two minutes in a glass filled with this solution By the use of this solution the pores of the hair follicles and of the sweat and sebaceous glands are rendered patent for passage of the cur-The site for the injection should be over rent some powerful muscle, such as the gluteus or the When in the gluteal region it is for the lymph streams, and the passive movements better to carry the injection through the fascia into

the muscle, but in other regions it should be made pleuro-pneumonia—at any rate, it had a lump on its in the subcutaneous cellular tissue Of course it is understood that the needle must be very sharp, and must have been previously disinfected with boiling Immediately water, and then thoroughly dried after the injection the moist electrodes are applied, the positive to neighboring tissue, while with the negative the operation strokes the seat of injection At first a weak current with considerable pressure is used, and this is increased gradually until the elevation made by the injection disappears sitiveness and pain usually disappear entirely in four or five minutes, the skin can be pulled up in folds, and should some little infiltration show itself, this can be completely dissipated by using the induction current two or three times

Wachsner has used this method more than a thousand times, in 45 cases Of the cases there were 25 of syphilitic disease, 12 cases of hæmorrhage, and 3 In the syphilitic cases a of nervous phenomena 1 100 solution of sublimate was used, from 8 to 9 mgr of sublimate being used for each injection the cases of hæmorrhage he used a solution of ergo tin, in equal parts of glycerine and water, o i gr The camphor used for injection being injected It may be was dissolved in 96 per cent alcohol suggested that this use of the induced current would be of great service when the blood-injections recommended and used by von Ziemssen are practiced If the method be as valuable as would seem at first sight, it is possible that in many cases, as Wachsner suggests, the stomach will have to perform only its normal work of receiving and digesting food

PUBLIC WEALTH VS PUBLIC HEALTH

Less than a month ago a notice appeared in the obituary columns of the daily papers of this city, showing that on February 3, 6, and 15, the three children of a family had died of diphtheria in Chicago, their ages being 6, 3, and 1 years respectively But this announcement caused no commotion or public talk in the city, and certainly none in the The matter was not brought before Congress, nor was there a meeting of State Governors to dis-It does not appear that the family cuss the matter was quarantined, nor that any investigation was made of the origin of this outbreak of diphtheria. Beyond the family left childless no thought seems to have been given to the fact that three children have been carried off by a preventable disease

There was immediately a great commo under jaw tion in the State, and in adjoining and distant States Telegrams were sent to Washington, and Congress made haste to pass a bill, creating a new official with a salary, and added him to the Department of the Interior, making this new official a sort of Bureau of Animal Industries, and more than this, the business of the cattle-drovers at the Chicago Stock-Yards was temporarily paralyzed in order to see if some other cows might not take pleuro-pneumonia from the one An embargo was laid on cattle from the place where the cow with the swollen jaw was found The Bureau of Animal Industries seems to have gone out of existence, and it was probably forgotten until a short time ago, when it was found that the embargo laid in 1886 has not been removed

Cattle are valuable animals, and it is very impor tant that, since we use them for food, they be kept as free from disease as possible But are they more valuable than children? Is it more important that cattle be kept healthy, and free from preventable diseases, than children? One diseased cow, it may be said, may cause disease in many human beings The same may be said of one child sick with an in But cattle are worth money, and fectious disease their loss is a positive pecuniary loss to the owner The same, and to a very much greater extent, is true of children

How many cattle die annually of pleuro-pneumonia as compared with the number of children that die of diphtheria-not to mention the other infectious dis eases? Is there any comparison between the num bers? Do not the examples that we have cited remind one of straining at a gnat and swallowing a camel? Do not the people of this country owe it to themselves to have more efficient and a more uni form system of supervision of the health of the people?

There is another thing in connection with this question—the compulsory notification of infectious Whether a municipal government does right in compelling such notification without com pensation or not, the fact remains it is the duty of It is probably the case the citizen to obey the laws in every city in which there is compulsory notifica tion, and certainly is the case in Chicago, that physi cians are influenced not to report infectious diseases It is not long since a physi by interested parties cian (an irregular) was called to see a child sick with measles in a certain hotel in Chicago He was called by the advice of the proprietor, and was influenced cow somewhere down in the State of Illinois had by the proprietor not to report the case, though at

the time there were a number of small children in mals The matter was, as far as possible, kept a profound secret in the hotel This is one way in which unthinking, careless, ignorant people, aided by legal physicians, toy with human life

Suppose it had been smallpox instead of measles The stake for the hotel proprietor to play for would have been so much the greater People that will not run from measles will run from smallpox ple living in the hotel would, in all probability, have been exposed to the infection before learning of its presence, and then would have scattered themselves around the city, to other hotels and boarding houses. thus creating new centres of infection The punishment for the concealment of infectious disease by a householder, and for non-notification by a physician, should be so severe that such things will be unprofit-Then, perhaps, there would be able in the extreme a considerable reduction in the death-rate from such diseases

THE DEATH OF HENRY BERGH

On Monday, March 12, Mr Henry Bergh, long prominent as the President of the American Society for the Prevention of Cruelty to Animals, died at his home in New York City To the medical profession, especially in the State of New York, he has long been known as the tireless and unremitting opponent of any and all experiments on animals But while his love for animals was at times carried to an excess of enthusiasm and zeal, and while he and his agents may have been at times more officious than judicious in enforcing the principles of his society, it must be remembered that his was a work that required enthusiasm and the most ardent zeal, that popular prejudice was against him from the first Bergh was undoubtedly one of the great reformers, and his work must be measured by general results To the hundreds and thousands that stand ready to look after the wrongs of human beings, there are but few-very few-that take any thought of the rights and wrongs of dumb brutes Bergh aroused and quickened the dormant sentiments of pity and kindness for animals He went about his work in the face of a storm of sneers, ridicule, and abuse that would have discouraged men with less courage, and not so large of heart It may be truthfully said of him that his work has bettered humanity, on the one hand his influence has brought to his aid the better and more refined classes of society, while his power taught human brutes that they could not wilfully torture dumb ani stomatology may join the Society

Municipal authorities have recognized the humane influence of his work, and State legislatures have made new laws for the protection of dumb animals, police powers have been granted, and dead laws have been reanimated

Looking at Bergh's work as a whole it must be said that it was, and still is, a great work Scientific men cannot, of course, look upon his attempts to abolish experiments on animals as other than the results of an honest though misguided zeal-the results of trying to fight an imaginary evil, a practice in which he could see nothing good But in the legitimate field of the society founded by him there is still much work to be done-and outside the City of New York

PROPERTY IN LECTURES

In The Journal of February 11, we asked and commented upon the following questions

"Is it proper for a medical reporter having access to the ordinary clinical lectures in a hospital, to attempt to report in full the clinical lectures of a member of the hospital staff, and furnish the same for publication, without submitting a line of his manuscript to the lecturer for his approval? Is it proper for editors or publishers of medical journals to receive and publish what purports to be verbatim reports of clinical lectures without any evidence that such reports have been approved by the lecturer, and without even allowing him an opportunity to read the galley proofs?"

In regard to this matter we have recieved the following from Judge M D EWELL

"In answer to this question of propriety permit me to say that this matter not infrequently comes up before Courts of Chancery for decision absolutely no doubt whatever that in thus publishing clinical lectures without the lecturer's consent a legal wrong is committed, for which the courts give an adequate remedy Should your readers desire the authorities for this statement I shall be pleased to refer to them, but I will not otherwise take up your space "

SOCIETE DE STOMATOLOGIE is the name of a medical society organized in Paris on February 6, for the purpose of studying the diseases of the mouth, the dental apparatus and the adnexa Dr Magitot was elected President, and Dr Galippe, 65 Rue Sainte-Anne, Secretary Laryngologists, rhinologists, otologists, ophthalmologists, and specialists in the field of

ASSOCIATION ITEMS.

PROPOSED AMENDMENTS TO THE CONSTI-TUTION OF THE ASSOCIATION

It must be remembered by the members of the Association that several amendments to the constitution will come up for adoption at the approaching meeting As they met with no opposition at in Cincinnati the last meeting and would then have been adopted had it not been for the rule requiring all amendments to the constitution to be before the body for a year, it is probable that they will be adopted and become part of the law of the Association at the next meet-The reasons for the amendments were fully stated by the Special Committee that proposed them The complete report of this committee can be found in No 26 of vol viii of The Journal posed amendments are as follows

A substitute for an amendment adopted in 1884 to

the second section of the constitution

Members by Application shall consist of such members of the State, County and District Medical Societies entitled to representation in this Association, as shall make application in writing to the Treasurer, and accompany said application with a certificate of good standing signed by the President and Secretary of the society of which they are members, and the amount of the annual membership fee, \$5 They shall have their names upon the roll and have all the rights and privileges accorded to Permanent Members, and shall retain their membership on the same terms

From the fifth section of the Constitution, relating to "Standing Committees," the first and third paragraphs should be stricken out, leaving intact only the second paragraph, relating to the "Committee of Arrangements" In place of the first paragraph to be erased, your committee recommend the insertion of the following important provision, viz

The General Committee or Council shall be composed of two members from each State and Territorial Medical Society entitled to representation by delegates in the Association, and from the Medical Departments of the U S Army, Navy, and Marine They shall be chosen by the mem-Hospital Service bers registered and present at each annual meeting, from each State, Territory, and from the Medical Corps of the U S Army, Navy, and Marine Hospital Service, acting separately, on the third day of each annual meeting, each delegation reporting the names of the members chosen to the Permanent they may be announced by him at the opening of the connected with the work of publication, must be en morning session of the fourth day. morning session of the fourth day At the first elec-) dorsed by the President of the Board of Trustees

General Committee, one of whom shall serve one year and the other two years, and at each annual election thereafter one member shall be chosen to serve for two years, thus making the term of office of members of the General Committee two years It shall be the duty of the General Committee, thus constituted, to organize by choosing annually a Chairman and Secretary, and such sub-committees as may be found necessary to facilitate the work that may be assigned to it, to meet annually at the place and on the day preceding each annual meeting of this Association, and as often during that week as may be necessary, to nominate, on the third day of each annual meeting, all the general officers of the Association (none of whom shall be members of its own body), the members of the Committee of Ar rangements, the Committee on Necrology, seven members of the Judicial Council, and three mem bers of the Board of Trustees for Publication for election by the Association, to recommend the place and time of holding the next annual meeting, and to consider and report upon all subjects that may be referred to it by vote of the Association ence of one-third of the whole number of members elected to the General Committee shall constitute a quorum for the transaction of business annual meeting of the Association, it shall be found at the close of the general meeting of the first day that a quorum of the General Committee is not present, it shall be the duty of the President and Perma nent Secretary to fill the vacancies in the Committee temporarily by selections from the lists of delegates registered as present from the States to which the vacancies belong

In place of the third paragraph, the following

The Board of Trustees shall consist of nine mem bers, three of whom shall be elected annually on the nomination of the standing General Committee, and It shall be the duty of shall serve for three years the Board to provide for and superintend the publi cation and distribution of all such proceedings, transactions, and memoirs of the Association as may be ordered to be published, and in such manner as the Association may direct, and in doing this, it shall have authority to appoint an editor and such assistants, and determine their salaries, and procure and control such materials, as may be necessary for the accomplishment of the work assigned to it further facilitate its work, it shall be the duty of the Secretaries of the Association and of the several Sections, during each annual meeting, or as soon thereafter as practicable, to deliver to the Board, or such editor or agent as it shall appoint, all such records of proceedings, reports, addresses, papers, and other documents as may have been ordered for publication, either in the general sessions or in the All moneys received by the Board of Trustees or its agents, resulting from the discharge of the duties assigned them, must be paid to the Treasurer of the Association, and all orders on the Treasurer for disbursements of money in any way It shall be the further duty of the said Board of Trustees to hold the official bond of the Treasurer for the faithful execution of his office, to annually audit and authenticate his accounts, and present a statement of the same in its annual report to the Association, which report shall also specify the character and cost of all the publications for the Association during the year, the number of copies still on hand, and the amount of all other property belonging to the Association under its control, with such suggestions as it may deem necessary

Should these provisions be adopted by the Association, the Permanent Secretary should be authorized to substitute the name "General Committee" for "Nominating Committee," wherever the latter occurs in other parts of the Constitution and By-Laws, and similarly the "Board of Trustees" for "Committee on Publication"

If these amendments are adopted, it will not change the mode of nominating officers for the meeting in 1889, since the proposed General Committee or Council which by the amendments will hereafter form the Nominating Committee, must be elected on the third day of the meeting, and will be announced on the fourth or last day, which would be too late for them to make nominations at the Cincinnati meeting If this General Committee is formed, it should, however, organize so that it will be an active standing committee, to do such business as may be necessary between the meetings of 1888 and 1889

SOCIETY PROCEEDINGS.

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, March 1, 1888 THE PRESIDENT, T M DRYSDALE, MD, IN THE CHAIR.

DR H A KELLY exhibited

AN ASEPTIC TWO-WAY CATHETER

A two-way catheter, which will conduct and discharge water and solutions with the utmost freedom and at the same time allow of perfect and ready cleansing after use, is a great desideratum light of the antiseptic surgery of to-day the use of In the degree dangerous, owing to the necessarily painfully tedious process of cleansing, and the impossibility of ever being able to assure ourselves that they are One of the best ever devised for the use of the upper and under surfaces the gynecologist is Bozeman's This has been modified by Fritsch and Oldshausen in such a way that the delivery pipe and discharge pipe are two separate pieces, so made that the delivery pipe enters the larger discharge pipe and is held in place by a ordinary dimensions of a placenta. It formed one

easier to clean than any previous forms, it was still difficult, and impossible to assure oneself I have now added my own modification to this instrument, making it now perfect in its utility and answering all antiseptic requirements

The syringe as constructed by me consists of three First, the delivery tube which conducts the stream from the hose connected with the reservoir into the uterus This tube is well curved, and at its entrance is furnished with a knob to hold the hose Its extremity ends in a button, with a series better of holes around and a little below the outer margin, in the form of a rose, so placed that the stream is thrown out on all sides and directed a little back-The remaining two pieces are the two lateral halves of the exit pipe, which is attached very simply by entering each end in the shallow collar under this rose, bringing them together around the inlet pipe and screwing the nut down on the thread on their upper end

Each side has a fenestra in it, near the point, and is scooped out near its upper end, so that when the two are fitted together there is a good sized hole When in use, water flies with force from the holes at the end, washes with it débris and fluid, which enter at once the large fenestra on the sides. are washed down and out of this large hole into the When out of use the cap is unscrewed, receptacle the halves fall apart, and every part which has come in contact with infection is at once exposed and readily cleansed The interior ought to be as highly polished as the exterior Mr Gemrig, of this city, has made these instruments for me in a highly satis-He has made one of solid silver factory manner for Dr Sweetnand, of Canada, which I exhibit here, with that I am now using as well as the older form

If the nomenclature is to be kept up as in the past, it is the Bozeman-Fritsch Olshausen-Kelly Catheter

DR KELLY also exhibited

A COTTON PACKER

This instrument has been many months on the shelf by my examining table, and is one of the few I am constantly using I have shown it to a number of my friends, and at a meeting of the alumni of the Woman's Hospital at New York this winter use is simply to pick up a loose wad of cotton placed near the vaginal outlet, and with the vaginæ properly exposed the uterus redressed, to carry it up into such two-way catheters as were commonly found in place in the fornices and pack in one wad after anthe surgeon's bag a few years ago, is in the highest other with perfect exactitude and any degree of firmness required It is made of a delicately tapering handle which balances nicely in the hand, terminating in three diverging tips, a little flattened on

DR B C HIRST exhibited

THE PLACENTA FROM A CASE OF UNIOVAL TWINS

It was very large in extent, having about twice the cap which is screwed down on it while in use This mass, with the most intimate anastomosis between will be understood better in examining my modification the two sets of feetal vessels. There was in this The objection to this still held, that although case hydramnion of one feetal sac

DR HIRST also showed

A PARIETAL BONI PRESENTING A SPOON-SHAPED DEPRISSION

It had been taken from an infant that died about The labor had been a difficult two days after birth one, terminated by the forceps, the child had presented by the vertex in R O P position, the pelvis was slightly flattened, head large, O I circumfer-At the corresponding point interence 36½ ccm nally there was a deep broad depression of the brain substance The child apparently died from congestion of, and serious effusion into, the brain

DR WM GOODEIL remarked that Ambrose Parc had compared these depressions to the indentation The indentation in this case was on kettle-drums After turning in the flat and narrow very typical pelvis, these indentations were very marked occupied then the temporal region and not the parietal, the shorter bi-temporal diameter being the one Hence in turning two mechanical advantages resulted, the small end of the cephalic wedge offered at the conjugate and also a cepnalic

diameter shorter than the bi-parietal

DR JOHN C DACOSTA wished to know if Dr Goodell thought turning could always be done in these cases? He spoke of a case that had occurred in his practice when the bone was much more depressed than in the specimen shown The whole left side of the head was bulged in by a large fibroid of the uterus, which fitted into the depression like a The pelvis was of good mortise and tenon joint shape and roomy, os uters wide open and soft, and yet the head, which was at or above the superior strait, in L O A position, would not descend on account the right side of the spinal column, opposite the third As the woman was in good condition of the tumor and nothing seemed to be going wrong, he let her After a little while, by the aid of alone for a time some manipulation, the head began to unlock from the tumor and rotated from O A to O P position, and the child was delivered alive

This case could not have been turned (as membranes had been ruptured and uterus gripped the child's body itself), and even if it could have been, there would probably have been a dead baby from pressure on the cord during the long delay that would ensue on delivering the head, as the tumor would most likely have locked under the baby's chin The forceps could not be put on, on account of ob-

struction to the left side by the tumor

DR GOODELL thought that Dr DaCosta would have had less trouble if he could have turned the He did not think the neck would have been He had been speaking before of the mechanical advantages only, and not of the difficulties in the performance of version

DR LONGAKER presented the following for DR

The case of Mrs B, æt 50, married at 15 years, HOLMES multipara, menstruation always scant and painful, is remarkable on account of a series of reflex symptoms, of death from exhaustion and from pain, without organic disease other than ovarian, and of simplicity of operation needed as revealed by autopsy

Mrs B consulted me April, 1886, having been treated elsewhere for muscular rheumatism Pains were of lancinating character along left sciatic, shoot ing down to ankle Examination showed ovarian tumor, probably cystic Prof Goodell confirmed diagnosis and advised operation, which patient then The chief complaint was and subsequently refused at first the pain posteriorly along left leg and thigh, which finally involved similar relations on right side In the course of a few months a persistent tremor attacked both lower extremities, at first alleviated by manual pressure, subsequently not, and later still extended to arms and hands and later yet to muscles of face and lips, giving much the appearance of violent chorea, interfering markedly with clear enunci

During the latter part of life there was oft-repeated and painful micturition, with bloody urine, with vio lent pain starting in lumbar region and shooting along into the bladder and urethra, raising a strong suspi cion of renal calculus

This, with the other lancinating pains, the tremors and nervous exhaustion consequent upon the many months' illness, caused great suffering, the patient often wringing her hands and grasping her hair in Hypodermics of morphia, 1/4 to 1/2 gr, gave agony markedly greater relief than same doses by mouth or The apparentin rectum, even frequently repeated

crease of tumor was very slow Autopsy indicated only slight omental adhesions The bladder, uterus, and the two Kidneys healthy attached cysts were removed a few hours after death The dermoid cyst has a long, slender pedicle, at tached to the left cornus uteri It was situated on and fourth lumbar vertebræ, covered by loops of small intestine and by omentum, to which latter it was slightly adherent. It was at first supposed to be a floating kidney which had undergone conversion into a cyst Its size, shape and location were sug The cyst contained choc gestive of such an origin No hair or teeth olate-colored sebaceous matter The wall contained calcareous plates ovary is the seat of a multilocular cyst the size of an The corpus uteri is average full term fœtal head undeveloped, the cervix constituting the larger por Evidences of chronic cystitis

tion of the organ

DR M PRICE said that this question was coming were present up daily, cases of pelvic disease were being con stantly treated by the general practitioner for mala ria, rheumatism, neuralgia and other kindred diseases, without making any investigation into the actual con dition of the patient In fact, malaria is becoming extremely fashionable, when there is no apparent reason for the condition He was then treating a case of ovarian disease, in a lady now 47 years old, was married at 15 years, contracted gonorrhoa from her husband at that time, has ever since remained sterile, with scant menstrual discharge and great pain from the approaches of her husband, sometimes the pain being agonizing She suffers at times from severe pain running down the left leg Upon examination the ovary was found to be as large as an orange, et

cessively tender, and when pressure was made in bimanual examination the patient went into convulsions on the table He did not know what relation this condition may have had in connection to the trouble in her early married life, of this he was sure, that it was the cause of her barren condition

DR LONGAKER also exhibited

THE POST-MORTEM SPECIMENS FROM A CASE OF CARCI NOMA UTERI

The following brief notes of this case are presented for Dr J S Gibbs L A, married, æt 39, always enjoyed good health until five years ago, when her last child was born Since that time she had suffered much from pelvic pains Menstruation had been excessive Patient first seen in June, 1887, when a diagnosis of carcinoma of the cervix was made The disease had invaded the vaginal walls and the pelvic cellular tissue

From this date I saw no more of the case until February 6, 1888 She had been free from pain, but

hæmorrhage persisted

Vaginal examination revealed advance of the dis-It provoked such a profuse hæmorrhage that applications of Monsell's sol were required to arrest It When the hæmorrhage was under control, pledgets of cotton saturated with terebene and olive oil (1-4) were packed against the cervix according to the plan of Betrin, of Geneva This medication di minished the offensive odor, but I strongly suspect it had something to do with the rather untimely demise of the patient

In a few hours from the time of the application she went into a somnolent state from which it was difficult to arouse her, with almost complete suppression of urine and strangury, and death in thirty-six hours A peculiarity of the case was absence of ca-

chexia and emaciation

Autopsy The cervix was extensively infiltrated The corpus shows a few nodules and ulcerated The ureters are dilated, as are also the pelves of the

Dr G E Shoemaker thought that the statement that death was probably due to an application of terebene should be carefully considered constantly using and observing the use of the drug internally in much larger quantities than could be absorbed from such an application, without sign of irritation Might not the death from uremia have occurred independent of its use?

DR LONGAKER believed that the application of the terebene did hasten death The strangury and suppression came on quickly after it had been used The case lacked some of the ordinary symptoms of

uræmia

DR WM GOODELL exhibited

A SPECIMEN OF CONJOINED TWINS,

which had been presented to him by Dr Junius F

Fuller, of Royborough, N C

The specimen was a perfect one The bodies were united at the hips and there were three feet in APEN ENPANSION VERSUS PURE AIR IN PULMONARY Some years ago an analogous living specimen of conjoined twins was on exhibition in this city, and he had brought them before his class at the

University and had given a lecture upon the subject From investigations then made he found that this form of conjoined twins was not a very rare one, as Aldrovanus and other old writers had described and figured them The specimen which he presented must have been aborted at the third month of uterogestation

DR GOODELL also presented

A SPECIMEN OF HYDROSALPINX

It was the largest specimen he had ever seen, although he had met with much larger specimens of pyosalpinx The case had been treated by many gynecologists and the true condition had not been There had followed the operation a recognized complete relief from pelvic pains, but menstruation had continued up to the present time The periods were, however, becoming less frequent was contended by some eminent surgeons that, when menstruation continued after the removal of the uterine appendages, some of the ovarian stroma must have been left behind, he wished to call the attention of the Society to the complete extirpation in this case of both ovaries and tubes Although the former were more or less adherent, it was evident from the specimen that not a particle of ovarian stroma was left behind

DR M PRICE said he had seen two cases in his practice where the menstrual discharge did not cease after the removal of the appendages In one case it lasted for a year and a half, in the other six months He had no doubt but that Dr Goodell's case would show the same result There was but little doubt in the mind of most operators that the removal had not been complete

PRESENTATION TO DR GITHENS

DR W H H GITHENS, who resigned the secretaryship of the Philadelphia Obstetrical Society the first of the year, after an uninterrupted service of eleven years, was presented this evening, in the name of the Society, with a very handsome mantel set, in cluding clock and side ornaments, in recognition of the very valuable services he had rendered the Society during his long term in office

Stated Meeting, February 22, 1888 W W KEEN, M D, IN THE CHAIR

DR THOS J MAIS read a paper entitled

CONSUMPTION

(See page 325)
DR. W W KEEN These are very practical ques-

tions presented for discussion Change of climate involves expense, separation from friends, interrup- service by calling attention to the fact that the con tion of employment Can we obtain equal benefits ditions to secure which consumptives are recommend by home gymnastics or change of employment? There is also a novel question raised as to purity of measures These are points that should be discussed

DR WILLIAM OSIER The last statement of the paper contains as ery important truth With imperfect | rect ratio between the percentage of cases of phthisis expansion there is a liability to clogging of the inter- and the breathing of impure air We often see a stitual circulation in the apices and accumulation of number of persons huddled into small, unventilated tissue debris which may afford a nidus for the devel- rooms, with filth and drink and all the factors of dis opment of the bacillus tuberculosis of activity of this interstitial circulation differs very such cases the men, who are engaged in active em much in different individuals little yet of the conditions which determine the de- streets, enjoy better health than the women, who velopment of tuberculosis like the old parable of the seed and the sower the tubs or sewing work nature of the soil will favor, retard, or prevent the That the bacillus of tubercle will not grow in every soil is demonstrated by autopsies in large of the treatment of incipient lung disease. A very general hospitals At Blockley, we will find in every hundred sections, say, fifteen or twenty cases with air in expanding the apices. In localities that are the usual lesions of phthisis, in fifteen or twenty warm, moist and low-like Florida, for examplethere are no excavations, the lung not extensively there is no such effect, and almost the sole benefit, tuberculous, but at the apices are small areas of induration, caseous nodules, and a few peripheral mili-The soil has not been congenial, and ary nodules the development of the bacillus was restricted Without bacillus, no tuberculosis, and that opinion ventilation of the lungs, reserving for Florida the is shared by ninety-nine out of every hundred clin- very weak and those liable to excessive hæmorrhage

icans of the day

department of physical education at the University of Pennsylvania, I had an opportunity of studying the effect of exercise on chest development Lads admitted with narrow lungs and supraclavicular depressions suffer, after moderate exertion, with embarrassment of pulmonary circulation is congested and there is evidently blocking of the blood current in the lungs After six or eight months of carefully regulated exercise, there is a change in did not confine himself to the topic of the paper and the local condition, no more obstruction is offered to the right side of the heart than elsewhere, the able manner blood-vessels respond to the extra demand put upon them With this free circulation goes an increase of say that I cannot accept the dictum, "no bacillus, them girth, from an inch to two or two and a half chest girth, from the chest girth gi Inspiratory exercises are inches in six months nearly always given these young men, especially those with that shape of chest which we are taught prescribed deep breathing, with or without movement side in the same employment, do the men become The arm is raised from the body to a After that the lifting right angle by the deltoid is done by the serratus magnus, the most important As the arm is carried nearer inspiratory muscle to the head, the insertion and origin of the serratus are approximated and the muscle works at a disad-For this reason expiration is practiced as the arms are carried up, and inspiration as they are Exercise should be made vigorous as a rule, do not strengthen the heart, but have a lo- a person inhales more air during sleep than in waking cal effect, whereas the object in these cases is to hours make the circulation free and the air-tubes pervious

DR C W DULLES Dr Mays has done good ed to live at high altitudes can be replaced by simple My observation, though limited, corresponds with that of Dr Mays, and I think that all of us have been struck with the fact that there is no di The condition ease, and yet apparently in blooming health In We know but very ployment, and the children, who run about in the In part, at least, it is have less active exercise and who bend over wash-

DR GEORGE E SHOEMAKER I heartily agree with Dr Mays that apex expansion is an important part important point is raised as to the action of rarefied as far as the climate is concerned, is from the patient's ability to be outside all the time Now would it not be better to send more of our patients to a climate where direct good is gained by the more thorough or to heart failure? In regard to impure air, we must DR EDWARD MARTIN While connected with the remember that many of those persons who enjoy good health in spite of their home surroundings, live out of door most of the time, the children in partic ular, living upon the doorstep or in the street, except In the same way at mountain in stormy weather and seaside resorts, the small and uncomfortable The right heart rooms drive visitors out into the air, and whether or not ozonized or rarefied, it is pure, out-of-door air

DR MAYS It is rather unfortunate that Dr Osler discuss the main points of the subject in his usual I purposely avoided all except an in cidental reference to the bacillus, but I must now bacilli need a soil in which to develop they should be able to penetrate into that portion of the lung which is hardly ever expanded in phthisical patients Why, if you take the two sexes and put them side by diseased in greater proportion than the women? Why this fondness of the bacilli for one sex? I must also dispute that point that ninety-nine out of every hundred clinicians accept this dogma Though born in Germany, the doctrine is already losing ground among the Germans

I wish in conclusion, to make a statement which I should have embodied in the paper, that, according to the latest researches, the apices expand more in the recumbent than in the erect position, therefore,

DR WM S STEWART presented

AN IMPROVED OBSTETRIC FORCEPS

I take it for granted that there is a large majority admitting their necessity, and the great benefit they are to the lying-in patient Therefore, I will content myself in endeavoring to point out the advantages of having parallel handles, so that the application of either blade first can be made at will, as the exigencies of the case may require The improvement is not restricted to any special form of blade, but can as readily be applied to the straight as to the curved, its use being equally effective with either form

The first object, for which I was most solicitous, was to be able to have an instrument that could be used readily in presentations in which it might be desirable to apply the second blade first, as some times in the second position of the head when jammed into the cavity of the pelvis and rotation to the antero-posterior diameter has been prevented by a narrow, contracted passage In all such cases there will be no difficulty in applying and adjusting the first blade, but occasionally it is impossible to apply the second in this condition of the presentation, the only remedy being to reverse the order by applying the second blade first, running the risk of injury to both mother and child in the recrossing of the handles in order that they may be locked before This we have overcome by havmaking traction ing the handles made parallel to each other, and without overlapping, as in the ordinary instrument Each handle has its own independent lock, the two being connected by a plain bar, which will admit of adjustment, no matter which blade is applied first

To overcome the danger of slipping, and to secure the grasp on the fœtus, it was necessary to devise some method of reversing the direction of the handles, in order that traction could be applied accomplish this a double lever was devised, one part on each handle, and each working on the same pivot or fulcrum, to this the traction is applied, resulting in a power perhaps superior to anything we could

have expected

The compression to the feetus is no longer in proportion to the power in the grip of the hand applied to the instrument, as in the cross-handles, but is regulated simply by the resistance to be overcome, consequently, all fear of the slipping of the instrument is obviated, and the only force that is necessary to be applied is for the delivery of the fœtus, serving at the same time for compression and trac-The compression, however, is controlled by a shoulder made on the toggle-joint, preventing any risk to the child, and its limit corresponding to the position of the blades of the cross-handled instrument when the handles are in apposition there be any irregularity of application, and consequent difficulty in locking, we have devised a coned hub with a winged nut, which, though the handles may be at an angle of twenty degrees, enables us to adjust them accurately The advantages of this summarized as follows either blade first

pression being regulated by the amount of resistance Fourth Greater facility for making traction

DR LONGAKER The only advantage of this modification of Dr Stewart's is that the forceps is not so This is due to the parallelism of the likely to slip blades, which is maintained even though the blades be not on opposite sides of the child's head, and in very large heads where it is difficult to recross the There is in existence another device for handles the same purpose—a very simple one—a mortise lock at the end of the handle Personally, I think the forceps introduced by Sir James Y Simpson can not be improved upon

Dr Packard I ought, perhaps, to speak with some diffidence on obstetrical matters, as my practice in that line has of late years been but limited Yet I can but recall the teachings of Professor Hodge, and the extremely practical instruction given the students of my day by Dr Joseph Warrington, which found abundant confirmation in my experi-

We were taught that the forceps should never be applied unless the os uteri was dilated or dilatable, that they should be introduced with the utmost gentleness, the surface of the child's head being the sole guide, that ready locking (and no force was ever to be used to effect this) was the test of proper appli cation, that under no circumstances was any leverage to be exerted by means of the mother's tissues, that the left hand of the operator (applied at the lock, the tip of the forefinger against the child's head, to detect any slipping of the blades) should be the fulcrum, the instrument being then used as a double lever, so as, by a gentle swaying motion from side to side, to coax the child's head through the This side to side movement was strongly advocated afterward by the late Dr Albert H Smith, whose experience and authority on such matters must be conceded Under all circumstances. except in certain abnormal positions of the child's head, the blades were to be applied with their long axes parallel with the occipito-mental diameter, and they had to be accurately opposed to one another in order to lock Now, it seems to me, in the light of my own experience, that the difficulty of recrossing the handles ought not to be such as to render a special mechanism needful in order to avoid it And I cannot but think that the deviation of the blades from parallelism, however brought about, involves danger

When the mother's forces are inadequate to effect delivery, I think the time has come to use the forceps, and to obviate the necessity of a long-continued grasping of the handles, they may be tied together with a handkerchief, or with any other convenient band, as soon as the blades are accurately applied to the head The compression so made is often necessary to the delivery, and on several occasions I have myself felt the bones of the head improvement, as experience has demonstrated, are give way under the grasp of the instrument, but the First The application of mother was unharmed, and the children lived As Second The impossibility of the to forcible traction, I have heard of the child's head slipping of the blades when properly applied Third being torn off, I have several times seen a strong Moderate and even compression, the degree of com- man brace himself with one foot against the bed, and
